Monte Albán (Zapotec): Geography and Culture

Ernesto González Licón
División de Posgrado, Escuela Nacional de Antropología e Historia, Mexico City, Mexico

Introduction

Monte Albán (500 BCE–CE 700) was the most important regional center of the Oaxacan region and political capital of the Zapotec. Its location on the top of a mountain at 400 m above the level of the Valley of Oaxaca was a defensive but also a valuable ideological aspect for the ruling elite. In 1987 Monte Albán and the city of Oaxaca were declared by UNESCO (United Nations Educational, Scientific and Cultural Organization) as World Cultural Heritage. Today, a great percentage of the central, ceremonial, and administrative structures and plazas has been restored and constitutes a great example of the political and social organization of the Zapotec culture in pre-Hispanic times but also a major touristic attraction.

Definition

Monte Albán was one of the first cities in Ancient Mexico and is today one of the archaeological zones that most impact the visitor by the dimensions of the Grand Plaza surrounded by temples and structures and above all by its location at the top of a mountain at the center of the Valley of Oaxaca. Monte Albán reached at its maximum development a population of 35,000 people; however, its founding, growth, and splendor as the capital of the Zapotec were the result of a long process of survival and colonization of the first inhabitants of the region and later of organizational strategies of the elites in the three valleys forming the great Valley of Oaxaca.

Key Issues/Current Debates/Future Directions/Examples

The foundation of Monte Albán toward the year 500 BCE. as the Zapotec capital was part of a process of economic and political integration as well as great growth and population concentration, which in turn increased the levels of social inequality in the region. During the previous phases, the dominant center was San José Mogote with other minor settlements around this site; however, between the year 500 and 300 BCE., San José Mogote lost almost its entire population and a new level of hierarchy was created with Monte Albán with over 155 new settlements around the cite (Blanton 1978: 87–91; Flannery and Marcus 1983) (Fig. 1).

The growth of Monte Albán was fast because for the next phase (MA-II, 100 BCE–CE 250), the city reached 4 km^2. With the Grand Plaza as the religious and administrative center of the site, with rectangular shape, oriented north–south is bounded by structures with temples and residences at the top, forming an impressive group. The temples were built with adobe on stone foundation walls; its walls were covered with stucco and painted. Their roofs were flat, supported by wooden posts supporting the walls. Some of the buildings that surround this square show the characteristic Teotihuacan style "*talud* and *tablero*" as decorative architectural elements (Fig. 2). In the northeast corner of the plaza, the ballcourt that had a ritual and religious sense is located with a north–south orientation. Another smaller ballcourt is near to the elite house of Tomb 105, in the northeast portion of the site (Blanton 1978).

Outside the ceremonial center, located at the highest part of the mountain, civil constructions and residential areas were distributed on the slopes, through terraces. Most of the domestic units included also a small orchard, one or several storage pit, and work areas. Although with multiple variants, these units kept a constructive pattern which highlights the presence of a central courtyard, with the rooms around it. Domestic groups lived in these houses for several generations. The size of the house, the central courtyard, and its proximity to the Grand Plaza or to a barrio center have been used as indicators of the socioeconomic status of each family, although there were also differences based on gender, age, and prestige reached within the group (González Licón 2009, 2011).

One particular element of the Zapotec culture is the custom of building tombs to bury their dead. The number, type, and form of these are very broad. They go from simple pits dug under the floor of the rooms without any apparent construction to the elaborate tombs with complex facades, jambs, and lintels with bas-reliefs, and multiple

Monte Albán (Zapotec): Geography and Culture, Fig. 1 General view of Monte Albán. (Photograph taken by the author)

cameras. Some have walls decorated with polychrome murals, with scenes of ceremonial and rituals, such as Tombs number 104 and 105 (Fig. 3).

Others, not as majestic as the previous ones, have marveled at the world for its content, as it was the case of Tomb number 7 (Caso 1969). It is a Zapotec, reused later by Mixtec, elite residence who decides to deposit their ancestors in this sacred place. So they removed part of the ceiling of the tomb, removed the remains that were there, and then put on the floor the skeletons of nine individuals accompanied by a large number of objects finely processed in a variety of materials such as gold, silver, jade, and turquoise among others (González Licón and Márquez 1990) (Fig. 4).

Funerary practices are part of the everyday life of peoples from its most remote past. These arise in accordance with the philosophy of human groups in each particular social context, thus vary in accordance with different cultures, with their social and economic organization, with the degree of technological development, with the ideology, with the complexity of his religious beliefs, and so on. Human being has always expressed a special cult for the afterlife and the boundary between the two, death.

Monte Albán (Zapotec): Geography and Culture, Fig. 3 Reconstructed south wall of Tomb number 105. (Photograph taken by the author)

The Zapotec tombs were incorporated in domestic architecture, usually located under the floor of the most important rooms, facing the central courtyard. The tomb was an enclosure that its owner would occupy after his death; among the Zapotec, the tombs are buildings that resemble the structure of the rooms they occupied in life. Example of this is Tomb number 5 of Suchiquiltongo, with the constructive characteristic style of phase IIIb–IV (650–800 CE), building replicas of the fronts of four rooms arranged around a central courtyard (Méndez 1990).

Monte Albán (Zapotec): Geography and Culture, Fig. 4 House of Tomb number 7. (Photograph taken by the author)

The funerary pattern typical of Monte Alban consisted in the reuse of graves; the most obvious example is found in Tomb number 7, where the richest site offering was located. The interesting thing about this case is that being a Zapotec tomb of phase IIIb, it was reused later in phase V by Mixtec. For this purpose, they took out everything Zapotec and later placed or rather spread across the tomb the remains of nine individuals accompanied by his offering. Not all the tombs were reused, for instance, Tomb number 104 was located with a skeleton in anatomical position, the offerings and the paint intact, although the latter seems to have been finished in a hurry, since "leakages" of painting can be seen in some strokes.

The motives in the murals appear to be symbolic, with complex representations of deities or priests with associated glyphs. The most ancient known, associated to the funerary architecture, mural is Tomb number 72 of Monte Alban, which represents several glyphs in red color. In other examples, processions of men or women singing in any religious ceremony appear. The murals are colorful and predominate the shades of red, white, yellow ochre, green, turquoise, blue, and black. The paintings in the tombs of Monte Albán phase IIIa show some resemblance with the frescoes of Teotihuacan, although in a style clearly Zapotec.

In addition to the murals, many tombs were accompanied by the typical Zapotec funerary urn. Both have been assumed initially as representations of gods, although currently is the notion that some of the murals as well as urns with anthropomorphic representations represent priests and members of the nobility. Many of these figures wear masks that relate to any of the main deities as *Cociyo* "Rain God," *Pitao Cozobi* "Corn God," or some other supernatural force; however, under the mask, the representation is distinctively human. Perhaps they were representations of ancestors, which could serve as intermediaries between them and the gods. The same respect and value that had old age was influenced not only by the accumulation of knowledge and experience that the elderly possessed but also because they were very close to arrive with the gods. Buildings on many of the tombs have offerings and burials associated, which suggest rituals related to the ancestors as members of the domestic group, who will continue many years after his physical burial.

Around the year CE 700, Monte Albán ceased to grow and ceased new constructions and maintenance of large buildings, so it was eclipsing gradually, although this does not mean that it would have been abandoned violently. The latest archaeological excavations on the site indicate

that a good number of houses remained inhabited at least until phase V (1300–1521 CE).

The fall of Monte Albán allowed the other cities that already existed strengthen, as well as the emergence of new ones. Cities in these phases IV and V did not maintain total control of the valley. They retained certain autonomy and created alliances through marriage and trade when it was convenient. It was a period of great social and political instability. The most important sites at this stage in the Valley of Oaxaca are Suchiquiltongo, Lambityeco, Mitla, and Zaachila (Blanton and Kowalewski 1981).

In phase V, the militarism in the Valley of Oaxaca expands, in the same way that was happening elsewhere in Mesoamerica. The Mexica arrives to the valley, who established themselves permanently in the area and finally conquered the cities more important as Zaachila, Cuilapan, and Mitla. It was however a temporary domain. Shortly before, they had arrived as groups from the Mixtec, engaging in continuous struggles for the domain of land and control of tribute. The Mixtec managed to dominate at a certain time and created a political center at Cuilapan (Marcus and Flannery 1996).

For this period there was contact with other groups by trade. There was also an intense artistic and technological exchange across styles and forms that are shared with the cultures developed in places away as the Basin of Mexico and in the area of Puebla and the Mixtec region with the Valley of Oaxaca. It is in this stage that Mitla was consolidated as the religious center of the valley. Mitla was one of the most important cities of the Valle de Tlacolula, outstanding among other aspects, by the construction of elite residences decorated with stone mosaics forming designs of great beauty and harmony. It was a dispersed settlement with constructions that took advantage of the small elevations of the land, with low platforms. Predominate within the site domestic complexes type Palace, with large central courtyards, under which tombs with elaborated architecture were constructed (Blanton et al. 1999).

Performing rituals in the region of Oaxaca and particularly in the valley was an important aspect for the maintenance of the ideology and group cohesion. Evidence of ceremonial and rituals have been recorded in all the periods of occupation and in most of the Mesoamerican urban centers. In the particular case of Monte Albán, it is clear that ideological control was important not only for the ruling elite but also for ordinary people who participated in them. The general population was participating in ceremonies and public rituals but also carried out ceremonies to the interior of the domestic group. For the ruling elite, the development of the ideological and symbolic world was a way to increase their power and control over their constituencies. As a corporate society, they focused more on domestic production. The cohesion necessary to achieve this inner wealth was achieved through management of the ideology suitable, materialized in rituals and ceremonies.

Monte Testaccio (Rome, Italy)

José Remesal Rodríguez
Catedrático de Historia Antigua,
Universidad de Barcelona,
Barcelona, Spain

Definition

Monte Testaccio is located next to the Tiber River, near the Porta San Paolo and the well-known pyramid-shaped tomb of Gaius Cestius, within what was the warehouse district, *horrea*, of ancient Rome (Fig. 1). An artificial hill with a perimeter of almost 1 km and a height of 50 m, Monte Testaccio was formed from the remains of fragments of millions of amphorae deposited there during the first three centuries CE. It is common to find stamped inscriptions on many of these amphorae. The toponym *Mons Testaceus* (Monte Testaccio in Italian) derives from the Latin word *testa*, meaning a fragment of pottery, hence the popular alternate name of "Monte dei Cocci." This hill stands out in the middle of the plain below the Aventine Hill and constitutes a singular element in the topography of ancient Rome (Aguilera Martín 2002) (Fig. 2). Although we do not have any ancient literary testimony of this hill, its enormous bulk was always evident both to the inhabitants of the city and to its visitors.

Historical Background

The first historical record we know of comes from an inscription dated to the eighth century CE that is preserved at the entrance of the Church of Santa Maria in Cosmedin, wherein the donation to the church of a portion of land that is in Testaccio is recorded. Over the centuries, theories were put forward that tried to explain its origins. For some the Testaccio had been formed because of the stacking of the remains of the fire of Rome in 64 CE during the reign of Nero. For others it had been formed from the waste of the pottery workshops located in its vicinity over the centuries. Some believed that it had been formed from the remains of cinerary urns from pagan cemeteries looted by Christians. As early as the Middle Ages, the idea that Monte Testaccio had been formed out of the remains of the vessels that arrived in Rome containing the payment of tribute from the provinces to the capital of the empire was spread; for this reason it was called *mons omnium terrarum*. In the Middle Ages, the area was uninhabited, and the place became the center of the Roman carnival. Carts with steers and pigs were thrown from the top of the hill, which the young men, paladins of every region of the city, then had to spear and carry a piece of meat home to their loved ones. In the middle of the sixteenth century, this festival was moved to the current Via del Corso. Also, in the middle of the sixteenth century, the Vatican artillery conducted target practice against the eastern side of the Testaccio. In the middle of the seventeenth century, wineries began to be created at the base of the mountain. They soon discovered that fresh air that maintained a constant temperature emanated from the interior of the mountain, and this helped maintain the wine. These cellars spread around the base of the mountain, and so to them we owe the current perimeter of the Testaccio. The Testaccio was presented as a bare hill that had already been compared to the

Monte Testaccio (Rome, Italy), Fig. 1 Roman settlement in the Testaccio area (Aguilera Martín 2002)

Monte Testaccio (Rome, Italy), Fig. 2 Aerial view of the Testaccio

Golgotha. In the eighteenth century, three crosses were installed on the mountain, and a via *crucis* ("way of the cross") was organized from the church of Santa Maria in Cosmedin to the top of the Testaccio; there is still a cross as a memory of a celebration that lasted until the middle of the twentieth century. The Testaccio was also a quarry for materials, as people took advantage of ceramic fragments for the foundations of buildings or to repair roads. In 1742 a communal edict was established that prohibited the removal of materials from the Testaccio under threat of very steep fines, although it must have been ignored because in 1744, the Comune was forced to issue a new order. In the nineteenth century, the so-called bacchanals of the Testaccio are well known in Rome; in fact it was to celebrate the feast of the harvest and new wine, festivals sung by all Romanesque poets, including Giuseppe Gioachino Belli. In the middle of the nineteenth century, with the creation of the new slaughterhouse in Rome, the area became a working-class neighborhood. It was also in the middle of the nineteenth century that the scientific studies of Monte Testaccio began.

It was W. H. Gomonde who first proposed that the Testaccio had been formed during the last centuries of the Roman Empire, having found a coin of Gallienus (Gomonde 1853). Shortly after this August Reifferscheid observed that the inscriptions that were on the amphorae were all in Latin, for which reason he proposed that they came from the western part of the Roman empire, since there were no texts in Greek (Reifferscheid 1865). Father Luigi Bruzza was the first to affirm that the materials in Monte Testaccio, as shown by the stamps on the amphorae, came from the Roman province of Baetica (Andalusia, Southern Spain) (Bruzza 1872).

When in 1872 the young Heinrich Dressel returned to Rome, after studying in Berlin, where he had worked with Th. Mommsen, he decided to devote himself to studying the materials of Monte Testaccio. Until then those who had been interested in the Testaccio had limited themselves to making a collection of amphora stamps.

Dressel decided to carry out a research project establishing that two conditions must inform the study: establish how the mountain was formed and when. He decided to divide the mountain into sectors, and each sector was divided according to its height. Dressel indicated whether the material he collected and inventoried was found in situ or if it was material that for any reason, ancient or modern turbation, was not in its original location (Fig. 3). He arrived at the conclusion that certain stamps were to be found in certain places. He could verify that all the material corresponded, fundamentally, to two types of amphora. One, on which almost all the stamps were found, corresponded to a type of globular amphora, which constituted most of the material deposited there. Other fragments, also frequent but in smaller quantities, corresponded to a type of amphora made with a clay of better quality than the former. One day in 1873, when he was on the mountain, a great storm allowed him to discover something he had been seeking for some time: on these amphorae were not only the stamps but also a series of painted inscriptions, so-called *tituli picti*, that remained hidden under a layer of lime that covered the fragments and that only became visible when moistened. The Romans had thrown lime on the fragments of amphoras, no doubt to eliminate odors and bacteria.

In Dressel (1878) presented the first results of his work, creating a system to organize the different types of stamps and explain their various contents. At the same time, he was able to decipher and explain the painted inscriptions (*tituli picti*). He was able to determine that, at least, there were four fundamental elements, which he defined with the Greek letters, *alpha*, *beta*, *gamma*, and *delta* (Fig. 4). *Alpha*, on the neck of the amphora, is an amount that Dressel was able to identify as the tare of the amphora (approximately 30 kilos). *Beta*, under *Alpha*, contains the name of one or more individuals, which Dressel interpreted as the name of the content producer. *Gamma*, under *Beta*, is again an amount that represents the weight of the net content of the amphora. The relation between the volume of the amphora and the weight of its content allowed Dressel to establish that the content was olive oil; the net content of oil was close to 216 Roman pounds, about 70 kilos of oil. These three inscriptions were written using a flat brush. To the right of these three inscriptions, next to the handle of the amphora, was written the annotation *Delta*, written with a hard point, a *calamus*, which showed that it was the control of the amphora at the time of filling. A barred R (*recognitum* or *recencitum*) clearly indicates that it was a control. The names of Baetican cities were mentioned – Hispalis (Seville), Corduba (Córdoba), and Astigi (Écija). This does not mean that all the amphorae were controlled in these cities, but these three were the capitals of three of the four *conventus* into which Baetica was divided, so the names of these cities indicate the fiscal district from which they were issued. The amount indicated in *Gamma* was repeated. Names appear in the nominative and the genitive cases that likely point to the individuals in charge of carrying out the control. On occasion, a toponym appears, in our opinion, the name of the precise place of embarkation and, in particular, the consular dating, the year in which the amphora was issued.

With this method Dressel was able to affirm the following: (a) that the Testaccio had been formed over a long period of time, since on its surface he had found consular dates between the years 145 and 257 CE and that, therefore, its beginnings should date much earlier; Dressel proposed that this should be fixed in the time of Emperor Augustus (reigned 27 BCE to 14 CE); (b) that it had been formed in an organized way, since he found the different dates in different concrete places; and (c) that almost all the material deposited there came from Baetica.

His claim that almost all the material came from Baetica received a rapid criticism. Hirschfeld claimed that it was material from Gallia, for he had also found many of the stamps that appeared in the Testaccio along the Rhone Valley and concluded that, therefore, the Testaccio amphorae containing wine had come from the Gallia. In 1912 Heron de Villefosse published two Gallic inscriptions in which characters known in the Testaccio appeared and showed that the individuals named in *beta* position in the Testaccio amphorae were not the olive oil

Monte Testaccio (Rome, Italy), Fig. 3 Distribution of stamps and *tituli picti* found by Dressel

M

Monte Testaccio (Rome, Italy), Fig. 4 (**a**) Dressel 20 type amphora with its *titulus* found in Testaccio. (**b**) Diagram of the titulus pictus on a Dressel 20 type amphora

producers but the merchants. This fueled the discussion about the origin of these amphorae. Dressel defended himself in his day by saying that the names of the cities that appeared in the Testaccio amphorae were names of Baetican cities. Perhaps what his contemporaries did not understand is that the immense majority of the amphorae, those that carried the inscriptions, belonged to a unique type (later called Dressel 20 amphoras) and that, therefore, they all came from the same region. In 1881 Dressel, along with Bruza, conducted a series of surveys in the Testaccio, which allowed him to confirm his hypothesis. All the material was published in volume XV, 2 of the *Corpus Inscriptionum Latinarum* (Dressel 1899). Almost at the same time that Dressel worked in the Testaccio, G. Bonsor was discovering in Baetica the workshops in which the amphorae that arrived at the Testaccio were produced, but it took a long time to know one another's works.

On the other hand, Dressel had the opportunity to study the amphorae found in the filling of the Castro Praetorio pit, north of the city of Rome (Dressel 1879). There he found a wide variety of amphorae and their inscriptions, which allowed him to establish a typological table in which he could distinguish different types and products contained in them and, in some cases, the origin of these products. Although Dressel had laid the

Monte Testaccio (Rome, Italy), Fig. 5 Hypothesis of material build-up in Testaccio (Rodríguez Almeida 1984)

foundations for the development of amphorology, it would still be a long time before it developed fully.

In the mid-1960s, M. Ponsich (1974, 1979, 1987, 1991) resumed the surveys in Baetica, finding new workshops that produced olive oil amphorae, identifying many new stamps, and E. Rodríguez Almeida resumed Dressel's surveys in the Testaccio, providing new and interesting data (Rodríguez Almeida 1972, 1984, 1989). Based on the data from Dressel, Rodríguez Almeida proposed that the Testaccio had been formed as a first platform, developed between the time of Augustus and 149 CE and then a second platform, west of the first, which developed from the Antonine era to the Severan era. He also considered that to the east of the first platform, there had been a small deposit with materials from the mid-third century (Rodríguez Almeida 1984) (Fig. 5).

Also, in the middle of the twentieth century, the development of underwater archaeology demonstrated that the amphorae constituted most of the cargoes of the ships. From this was triggered, first, the interest in identifying the different types, their places of production, and their chronologies and, consequently, the study of the economic significance of this trade. In 1978 the first international congress on olive oil production and trade in antiquity was held (Blázquez Martínez 1980) and in 1982 the second (Blázquez Martínez and Remesal Rodríguez 1983). From this moment the Testaccio, a landfill for the Romans, became an exceptional archive for the study of the ancient Roman economy. An archive that had the peculiarity of referring to a single product, olive oil, whose documentation came almost exclusively from a single Roman province, Baetica. The Testaccio offers an abundant documentation that is not only chronologically serialized but also unique for the study of the Roman economy (Remesal 2013).

International Perspectives

The study of the presence of Baetican olive oil in Germania (Remesal Rodríguez 1986, 1997) gave rise to a new interpretation of the Roman economy. Up to this moment the theoretical discussion on the Roman economy was divided between two

opposing poles, the so-called primitivists, who understood that the Roman economy had little in common with the modern economy and "modernists," who understood that there were not many differences between the economic structures of the Roman world and ours. In any case, it was understood that the Roman state had intervened little on the economic development of imperial Rome. The abundant presence of Baetican olive oil amphorae in Roman military camps in Germania, amphorae containing an exogenous product and foreign to the Germanic diet, prompted Remesal Rodríguez to propose that these had reached the *limes* through a redistributive system organized by the Roman state, which led him to propose that the *praefectura annonae* was not only responsible for organizing the supply of wheat to Rome but intervened on many other products not only to maintain peace in Rome but also to ensure the supply of the army. Among such products there was, ever since the time of Augustus, olive oil, one of the determining elements of the Mediterranean diet, as evidenced by the existence of Monte Testaccio, given that its origins must be traced, as proposed by Dressel (1878), to the principate of Augustus (27 BCE to 14 CE). This led him to discuss the relationship between the political evolution of the empire and the evolution of food control and to study the role of each province of the empire in terms of this need of the empire to redistribute some fundamental products, food or not. In this way, the state became the engine of certain economic relations (Remesal Rodríguez 2011).

These theories are today one of the central points of the debate and interpretation of the economic organization of the Roman Empire. This approach needed new approaches in order to discuss the issue. These theories have been accepted by some and criticized by others (Remesal Rodríguez 2011, 41–42 collects references to both). Criticism has gone in two directions: on one hand, the relative use of the Atlantic route as the main route of trade between Baetica and the northern provinces, against the traditional view that the main route was the Rhone Valley (Wierschowski 2001; see my replica Remesal Rodríguez 2002). Tchernia (2002) joined the discussion, who in 2011 reprinted his previous article without taking into account my answer to Wierschowski (Tchernia 2011; 2012). On this issue see our latest work (Rubio-Campillo et al. 2018). For perspectives related to the administrative organization of the Roman Empire, see Eck (2006) and my own response (Remesal Rodríguez 2008).

In 1989, the CEIPAC research group (website: http://ceipac.ub.edu/) was created at the University of Barcelona under the direction of Prof. J. Remesal Rodríguez. This group has two purposes: to create a computer-based corpus in which all the known amphoric epigraphy was collected and to carry out new excavations on Monte Testaccio.

CEIPAC's epigraphic corpus currently contains more than 43,000 records, stamps, *tituli picti*, and graffiti on amphoras, which contain almost one million pieces of data. It was created as a relational database in the Structured Query Language (SQL) system and has an ICT system (information and communications technology), which allows any researcher, from anywhere in the world, to initiate this type of research. This database is integrated into the project *Epigraphie amphorique* of the Union Académique Internationale, a project in which various academies participate.

The CEIPAC (Centro Para El Estudio De La Interdependencia Provincial En La Antigüedad Clásica) database now has been migrated to an ontological system, which allows new possibilities for analyzing inscriptions, which we can now relate to the information collected in other databases. The interaction between historians, archaeologists, computer scientists, mathematicians, and physicists working on social networks is opening new perspectives to the development of research on the Roman economy (Remesal Rodríguez 2017).

Excavations at Monte Testaccio have been carried out since 1989 under the direction of Professors Blázquez Martínez (†2016) and Remesal Rodríguez (Blázquez Martínez and Remesal Rodríguez 1999, 2001, 2003, 2007, 2010, 2014; Blázquez Martínez et al. 1994). The excavations in the Testaccio have two purposes: to

come to better understand the formation of the mountain itself and to increase our volume of data.

Our excavations have allowed us to better understand the order of deposition of materials and propose a hypothesis about the composition of the mountain, in which there are only the remains of amphorae. Of the ancient extent of Monte Testaccio, only the northern boundary is conserved, and it has lost a lot of material on its eastern, western, and southern sides. We have studied the density and the volume of the hill which allows to affirm that at present the remains of some 25 million amphorae are still preserved. Of these, between 80% and 85% come from *Baetica*; between 10% and 15% depending on the time come from North Africa, Libya, and Tunisia; and the remaining, no more than 1% or 2%, is made up of amphorae from the eastern Mediterranean. The scarce presence of African material would be integrated into the discussion about the intervention of the Roman administration in the distribution of food products. So surprising is the scant presence of African oil amphorae in the Testaccio as in the western provinces of the empire. African amphorae in the Testaccio appear very fragmented, so it is now difficult to understand their *tituli picti*. On the other hand, seals are also scarce, particularly on Leptin amphorae; on those of Africa Proconsularis, they are more frequent in the middle of the third century CE, and they come, fundamentally, from Hadrumetum and from Sulectum (see Revilla Calvo 2014).

Monte Testaccio was formed from a systematically organized platform, for which the entire Baetican olive oil amphorae were taken there; some of them had their bottom broken and were placed forming a row that determined the limit of the discharges; these amphorae were then filled with other fragments to make them heavier and fix them better to the ground; behind them they proceeded to unload, fragmenting the rest of the amphoras right there. Subsequently, another row was formed, and the process was repeated, thus creating walls with an inclination close to 45° (Fig. 6). When these platforms reached a certain height, another one was built a little lower, forming a stepped pyramid (Fig. 7).

Later, when the maximum height of the first platform was reached, around 149 CE, the steps that had been forming were filled in. In any

Monte Testaccio (Rome, Italy), Fig. 6 Wall made of amphoras in Testaccio

Monte Testaccio (Rome, Italy), Fig. 7 Material build-up on Testaccio's southern slope

case, it is not necessary to think, as proposed by Rodríguez Almeida, that there must have been a first great platform but that from a nucleus it was extended in one direction or another depending on the immediate interests of the moment; therefore, in our excavations we have found deposits of the same year in different places and heights. One of the novelties about the formation of the mountain is to have been able to verify that what Rodríguez Almeida considered as a small discharge from the middle of the third century CE is, in fact, the remains of a third platform that expanded all along the eastern side of the mountain (Fig. 8). In addition, our surveys of 1990–1991 and 2009 have allowed us to delimit the point of contact between the two platforms indicated by Rodríguez Almeida.

As a whole, our surveys have allowed us to know in a more precise way the distribution of the material in what we can call the "skin of the mountain," defining, to a large extent, the evolution and growth in height of the deposits. To the dates obtained by Dressel, we have been able to add new ones by increasing the known chronological series, particularly relevant are the dates relevant to the period of the reign of Commodus, as well as the Severan and post-Severan periods. We have identified numerous *tituli picti beta*, that is, names of merchants hitherto unknown, and we have also found a large number of *tituli picti delta*. At this point we can offer with much better documentation for their interpretation, as well as a considerable number of new stamps and the possibility of better dating for many other extant examples that were already known. With regard to African amphorae, Monte Testaccio is also our best source of information to date the typological-chronological evolution of African amphorae dedicated to the transport of olive oil. This is due to the fact that in the Testaccio, we have also found a large number of stamps on these amphorae that we have been able to date, and we also have a series of hitherto unknown *tituli picti* on these amphorae. The same can be said in

Lámina I.- Propuesta sobre la distribución de las diversas plataformas del Testaccio.

Monte Testaccio (Rome, Italy), Fig. 8 Current hypothesis of the formation of the mound

relation to the amphorae coming from the eastern Mediterranean.

Future Directions

The Baetican olive oil amphorae are in a paradigmatic situation in relation to other amphora types:

1. We know their places of production in Baetica.
2. They are the most frequently stamped amphorae. The stamps on Baetican olive oil amphorae (Dressel 20 type) are composed of the *tria nomina* of a free individual (e.g., citizen or freedman) which we consider the name of the person who ordered the amphora. To these stamps are added others in which the name of the workshop is recorded; others, however, collect a servile name, a *cognomen*, which we interpret as the name of the potter or workshop leader. Sometimes, all of this information can appear combined in a single stamp. Also frequent are the graffiti *ante cocturam*, made when the clay was still soft (i.e., pre-firing). Sometimes these are acronyms that indicate quantities, sometimes names appear, and in others a calendar date (day of the month) or a consular date (year) appears.
3. Baetican stamps were distributed throughout the western part of the Roman Empire.
4. We have the information obtained from Monte Testaccio. First, thanks to the dates obtained in the Testaccio, we can date many of the stamps that archaeologists find in their excavations throughout Europe, so we can help them date their excavations. But since we know the place of production of many of them in Baetica, we can help them understand the relationships that were established between Baetica and the findspot, which, in addition, helps to raise issues related to the organization of trade between the place of production in Baetica and the place of final deposition that is under study.

At a typological level, the Baetican olive oil amphorae offer some possibilities for analysis that can facilitate an understanding of the evolution of the amphora types and the organization of work within each of the production centers. For example, by relating the production of amphorae of a certain production center with the stamps that appear on them, we have been able to establish that various hands have produced amphorae that have been stamped with the same stamp, that is, the person in charge of stamping it was different from the people who made the amphorae, which helps us to understand the management system of the workshops.

The importance of Monte Testaccio lies in its significance for the study of the economic history of the Roman Empire. The fact that the Baetican olive oil amphorae are the most widespread in the western part of the Roman Empire allows us to study, through them, the trade routes and the structure of relations between the Mediterranean provinces and the central European provinces.

The *tituli picti beta* put at our disposal a large number of names of actors linked to the world of commerce in the Roman Empire. Studying the relationship between these characters and identifying their period of activity and their links with other characters reveal the structure of the organization of trade in the Roman world and the relationship between public and private in this area.

The *tituli picti delta* show, in its development, the changes in the administrative organization of the Roman Empire. This study allows for a better understanding of the evolution of the intervention of the administration in the economic development.

The progress of these studies requires the development of formal methods that enable each of the different elements in their category to be compared with each other. Stamps, *tituli picti*, and graffiti, at the same time, compare the information they offer us as a whole, that is, to be able to establish the link between these three types of documents. This would allow to reach some very specific analytical possibilities, difficult to do with other materials.

The current discussion seeks to define the relationships that existed between political and economic power in imperial Rome, based on the idea that the emperor was forced to maintain social peace in Rome, which, as Juvenal said, consisted

of *panem et circenses* ("bread and circuses"). Securing the food supply of Rome and its army was the emperor's first obligation. This fact conditioned the political evolution of the Roman Empire. Defining the role played by each province in this concert is a task for the future (Remesal Rodríguez 2011).

Monte Verde, Archaeology of

Tom D. Dillehay
Department of Anthropology, Vanderbilt University, Nashville, TN, USA

Introduction

Monte Verde is located in south-central Chile. The site is an open-air campsite on the banks of a small stream, surrounded by sandy knolls, small bogs, and damp forests that have been there since late Pleistocene times. The bog later developed in the stream basin, covering the abandoned site under a layer of peat. Because the lack of oxygen in the bog inhibited bacterial decay and because the constant saturation prevented drying for thousands of years, all kinds of organic materials that normally disappear from the archaeological sites have been preserved. An interdisciplinary research team of more than 60 scientists has studied the remains excavated from two areas at the site, called Monte Verde I and Monte Verde II.

Key Issues

Monte Verde II exhibits the remains of 10-m-long tent-like structure made of wood and animal hides. The frame was constructed of logs and planks anchored by stakes, and the walls were poles covered with animal hides. Several pieces of cordage and string made of reed wrapped around wooden posts and stakes, recovered among the architectural remains, show that the people planned a lengthy stay. The tent's dirt floor was embedded with hundreds of microscopic flecks of hide tissue, suggesting that it was covered with animal skins. On the floor of the tent were brazier pits lined with clay and surrounded by stone tools and the remains of edible seeds, nuts, and berries. Outside the tent were two large communal hearths, a store of firewood, wooden mortars with their grinding stones, and three human footprints near one of the large hearths. All these remains indicate tasks, primarily food preparation and consumption, tool production and maintenance, and the construction of shelters.

In a second structure, wishbone shaped in ground plan and made of wooden uprights set into a foundation of sand and gravel hardened with animal fat. Parts of gomphotheres and paleo-llama carcasses were butchered, hides were prepared, and tools were manufactured in and around the structure. Eighteen probable medicinal plants were found inside the structure – the same species the Mapuche people, who live in the area today, use to treat various diseases. Although some of these plants grew locally, about half came from coastal environments approximately 70 km to the west, and one was found only in arid regions about 700 km to the north. Since only the medicinal parts of the plants were found in the site, we know they had only one use to the Monte Verdeans.

In addition to medicinal herbs, the remains of a wide variety of edible plants were recovered from the hearths, living floors, and small pits, along with the remains of gomphotheres, paleo-llama, small animals, and freshwater mollusks. Aquatic plants from distant freshwater marshes and lagoons of the flood plain and from brackish marshes of the river delta provided the greatest variety and, along with meat and wild potatoes, the bulk of the diet. Most of these ecological zones are located far away along the Pacific shoreline or in the Andean mountains. The presence of exotic foods, including seaweed, and other items at the site shows that coastal habitats also provided important resources to the Monte Verde economy.

The wooden artifacts excavated at the site include digging sticks, mortars, fragments of two

lances, stakes, and the poles used for building the tent. Bone artifacts consist of a baton for striking flakes off stones, tools made of mastodon tusks, and probable digging and prying tools. Three different stone tool technologies also exist at the site, including bifacial tools, unifacial implements and waste debris, and grinding stones.

The distinct living structures, features, and concentrations of specific materials at the site suggest that occupation was continuous and that portions of the site were used more intensively than others. Different kinds of artifacts give evidence of a wide variety of activities to be done. One living space, for example, contained stone artifacts made of quartz coupled with edible fruits and tubers from plants that grow only in brackish estuaries, suggesting that the occupants may have specialized in collecting resources from the coast. Elsewhere in the living tent, stone scrapers and pieces of animal skin were found in a hide-working zone. The internal division and size of the tent suggests that people had a mixed hunting and gathering economy focused on many different ecological zones. A long sequence of radiocarbon dates on both different materials from the site places the Monte Verde II occupation at about 12,500 B.P.

Buried in a different area of Monte Verde, we found a possible earlier occupation, Monte Verde I, with 26 stone tools and three burned clay features. Radiocarbon dates placed this possible occupation around 33,000 years ago. Although the geology is intact, the radiocarbon dates are valid, and the human artifacts are genuine, the research team is very hesitant to accept this older level without more evidence.

The 12,500 B.P. Monte Verde II component represents a settlement that practiced a generalized economy throughout most of the year. The archaeological evidence suggests that the settlement was formed by a small group of colonizers who lived along the banks of the small stream. Although few contemporary sites have been found in the Americas, it is probable that the people at Monte Verde were part of a low-density population adapted to the cool, temperate forest of south-central Chile after deglaciation.

Montelius, Oscar

Poul-Otto Nielsen
The National Museum, Copenhagen, Denmark

Basic Biographical Information

Gustav Oscar Montelius (1843–1921), Swedish archaeologist, professor and keeper of National Antiquities, studied history and Scandinavian languages at the University of Uppsala 1861–1869 (Fig. 1). He was a close friend with Hans Hildebrand (1842–1913), the son of Bror Emil Hildebrand (1806–1884), the Swedish keeper of National Antiquities. The two young students were both influenced by the advances in geology and paleontology in France and by Darwin's *On the Origin of Species* (1859). During his studies, Montelius worked as an assistant at Statens Historiska Museum in Stockholm, where he and

Montelius, Oscar, Fig. 1 Oscar Montelius (1843–1921)

H. Hildebrand took part in creating a new, permanent exhibition of archaeological finds that opened in 1866 and was organized according to C. J. Thomsen's Three-Age System. Montelius' doctoral dissertation was about the Iron Age in Sweden (1869). He worked as an antiquary (curator) at the Historical Museum (1868–1907) under the direction of H. Hildebrand, whose successor as keeper of National Antiquities he was 1907–1913. He obtained the title of Professor *h.c.* in 1888, was conferred the title of Dr. *h.c.* in Greifswald 1906, and was offered the position as the director of the Museum für Völkerkunde in Berlin 1907, an offer which he declined. Montelius was the editor of two important periodicals: *Svenska Fornminnesföreningens Tidskrift* (1884–1905) and *Nordisk Tidskrift* (1879–1921).

Major Accomplishments

Montelius' first major work was *Sveriges forntid* (Swedish Prehistory) (1872–1874), the first survey of the culture history of prehistoric Sweden confirming the Three-Age System of C.J. Thomsen. The survey was updated in later editions, and his *Minnen från vor forntid* (1917) has remained a standard catalogue of Swedish Stone and Bronze Age antiquities. In the book *Om tidsbestemning inom bronsåldern* (1885), Montelius divided the Bronze Age in six periods. His chronological scheme is still being used today. He also divided the Stone Age in five and the Iron Age in eight periods.

Montelius was aware that in order to date the Scandinavian prehistoric periods, it was necessary to connect them with historically dated material in the Near East and the Mediterranean. So he became the first Scandinavian archaeologist, who systematically studied prehistory on a continental scale. For 15 years, he spent part of his time on journeys to museums in Europe, especially in Germany, Switzerland, and Italy. The Swiss lake dwellings and grave finds being excavated in Northern Italy provided important new material that allowed comparison of find material north and south of the Alps linking the Scandinavian sequence to the Mediterranean. Montelius worked out chronologies in a series of publications: *Die Bronzezeit im Orient und in Griechenland* (1892), *La Civilisation primitive en Italie* (1895–1910), *Pre-Classical Chronology in Greece and Italy* (1896), *The Tyrrhenians in Greece and Italy* (1896), and *Die vorklassische Chronologie Italiens* (1912). Montelius was convinced that the roots of civilization lay in the Near East, and he saw the spread of civilization as waves of diffusion and migration from the Southeast. The diffusionist view was expressed in *Der Orient und Europa* (1899) and in *Die ältere Kulturperioden im Orient und in Europa* (1903–1923). Montelius constructed a timescale that became widely used and which was not surpassed before later in the twentieth century, when radiocarbon datings opened up for a longer chronology and challenged the diffusionist paradigm (Renfrew 1973: 20–47).

Beside as a diffusionist, posterity has also labeled Montelius a typologist. The ordering of types to form sequences, often from the simple to the more advanced, analogous to biological evolution, was initially used by H. Hildebrand and developed by Montelius, who described the method in the first part of *Die ältere Kulturperioden*. Opposition to the method was expressed *i.a.* by the contemporary Danish archaeologist Sophus Müller. In reality, Montelius did not construct his chronologies using typology alone but based his chronological sequences

primarily on find combinations (Gräslund 1987: 70–85). Whether or not typology can be used as an independent method has been a matter of discussion through the twentieth century, especially among Swedish archaeologists (see further readings, Malmer in Åström (ed.) 1995).

Monumental Architecture in Precontact Polynesia

Jennifer G. Kahn
Anthropology Department, College of William and Mary, Williamsburg, VA, USA

State of Knowledge and Current Debates

The islands of the Eastern Polynesian triangle, bounded by the Hawaiian Archipelago, New Zealand (Aotearoa), and Easter Island (Rapa Nui) and those of Western Polynesia, which includes Tonga and Samoa, were home to diverse indigenous societies. Such groups were organized as chiefdoms and archaic states prior to European contact (Kirch 2017). As with other complex societies worldwide, the power and authority of Polynesian chiefs were materialized in diverse ways, often through the construction of monumental architecture. Before launching into a discussion of historical trends and current research on Polynesian monumental structures, we must first ask: What constitutes monumental architecture in Polynesia?

Historical linguistics document a long history of shared Polynesian terms related to ritual structures, some of which become elaborated as monumental sites in later prehistory. The Proto-Polynesian word ∗*malaqe* is robustly reconstructed from 25 cognate reflexes in different Polynesian languages and dialects (Kirch and Green 2001, Table 9.2). Throughout Polynesia, these reflexes of the ancient word ∗*malaqe* reference ritual or ceremonial spaces, yet such sites likely varied greatly in architectural form and function. At European contact Polynesian monumental sites encompassed more than just ritual-use sites and included structures with a wide range of form and

function, including sites with ceremonial use, elite residential use, and those used in warfare/competition. Consequently, a variety of stone architectural sites, from temples to tombs, have been classified as monumental architecture in Polynesian surface surveys.

The question of how to define and operationalize the term monumental is still debated in Polynesia, similar to other regions worldwide (Osborne 2014). Many archaeologists in Polynesia focus on the size and scale of the structure as the most important characteristic of monumentality. Typically, size and scale are treated in a relative fashion, with the largest monuments considered "monumental." For example, in a Tongan case study, Clark and Martinsson-Wallin (2007; see also Pulemelei examples in Martinsson-Wallin 2007, 2016) discussed massive mounds with greater than 2500 m^2 volume as monumental structures for chiefly residence or burial and as foci for ceremonial and religious activity. Yet in introducing a recent edited volume on Pacific Island monumentality (Martinsson-Wallin and Thomas 2014), Martinsson-Wallin (2014) took a more holistic approach, arguing that monuments are durable sites with massive social meaning (i.e., monumentality). Whether taking a scalar or social landscape approach, archaeologists in Polynesia agree that diverse forms of monumental architecture are found in the region during the precontact era.

Generalized Types of Polynesian Monumental Architecture

Monumental structures in Polynesia tend to coalesce around several broad categories: mortuary structures, ritual sites, elite residences and elite specialized-use structures, and fortifications. Mortuary structures include burial mounds, such as Tongan *fa'itoka*, mounds with gravel paving or coral slab facing, *malae*, and *langi*, the latter served as royal burial mounds of the highest ranking chiefs (Fig. 1) (Burley 1998; Clark and Martinsson-Wallin 2007; Kirch 1990; see also Sand 1993, 1999 for 'Uvea). Monumental ritual sites in Eastern Polynesia include the well-known *marae-ahu* complexes with temple and altar complexes well distributed on the landscape (Figs. 2 and 3) (Campbell 2006; Kahn and Kirch 2014; Kirch 1985; Kirch and Green 2001; Millerstrom 2006; Molle 2016; Rolett 2010; Stephens 2016; Wallin 1993). Perhaps the best-known structures in the *ahu-marae* complex are the Easter Island *moai*, which sit on stone-faced *ahu* or altars (Martinsson-Wallin 1994). Yet large-scale temples are also found throughout Eastern Polynesia, notably Hawaiian *heiau*, Marquesan *me'ae*, and Society Island and Tuamotuan *marae*.

Large-scale domestic sites, oftentimes with elaborate architecture and numerous auxiliary structures, have been associated with high ranking elites in many Polynesian archipelagoes (Allen 2010; Clark and Martinsson-Wallin 2007; Davidson 1974; Kahn 2005, 2016a; Kirch 2010; Martinsson-Wallin 2016; Weisler and Kirch 1985). While such sites are often not truly massive in size, they are much larger than the average domestic sites in the region, thus lending themselves to monumental nomenclature according to the relative scaling fashionable in the region. Kirch (2010: 166–171) recently argued that Hawaiian chiefs and their retinues lived in "palace-like" royal complexes. These were often were large in size, were constructed from specialized materials, and were found in close association with monumental temples. Other Polynesian contexts also have elite specialized structures that are frequently large in size, such as stone-faced wells for bathing, star mounds which served as pigeon snaring mounds or chiefly sitting mounds in Samoa and Tonga (Fig. 2) (Burley 1996; Clark and Herdrich 1993; Sand et al. 2018; Quintus and Clark 2019), and council meeting platforms in the Society Islands (Fig. 3) (Kahn and Kirch 2014). Such sites have an air of monumentality when compared to other architectural sites recorded in regional settlement patterns. In the Tongan context, Freeland et al. (2016) have noted how these large specialized structures were visible displays of chiefly prerogatives (see also Burley 1996; Kirch 1988); similar arguments have been made for specialized elite structures in the Society Islands and Hawai'i (Hommon 2013; Kahn in press; Kahn and Kirch 2014; Kirch 2010). Yet variability exists, as Quintus and Clark's (2019) recent investigation of Samoan star mounds

Monumental Architecture in Precontact Polynesia, Fig. 1 Some forms of monumental architecture found in Western Polynesia: Upper, Langi tomb, Lapaha, Tonga. (Modified from Clark et al. 2016, Fig. 1); Lower, star mounds, Samoa. (Modified from Herdrich 1991, Fig. 1)

Monumental Architecture in Precontact Polynesia, Fig. 2 Restored Marae ʻĀrahurahu, Paea, Tahiti, Society Islands. *Marae*/*ahu* is to the right, pavement is in the middle. (Photo courtesy of Heidy Baumgartner Lesage and Pierre Lesage)

highlights their role in status negotiation between individuals (among chiefs, among chiefs, and talking chiefs) and the group (between titled and untitled individuals).

Fortified sites in Polynesia have also garnered attention for their monumental size. Ditch and moat systems and ridgetop forts required massive modifications to the landscape and often covered large footprints (Anderson and Kennett 2012; Best 1993). While monumental ritual sites were not commonly constructed in southeastern Polynesia, large fortified sites reached their apogee there, including highly visible ridgetop villages in Rapa and *pa* complexes in New Zealand (Allen 2016; Anderson 2018; Kennett et al. 2006; Sutton et al. 2003). Finally, while not commonly considered monumental by archaeologists in the region, certainly the scale of landesque capital intensification in some archipelagoes, such as Samoa with its ditch and parcel terrace complexes (Quintus et al. 2016) and Hawai'i with its stone-faced irrigation complexes (McElroy 2007), could be considered by some to reach monumental proportions in localized contexts.

Historical Trends

As synthetic studies of Polynesian archaeology have noted, early salvage ethnographers and cultural historians from the 1920s up until World War II completed important field archaeology in the Pacific Island region (Burley 1998; Burley and Addison 2018; Kirch 2018). In Polynesia, a number of researchers mapped stone structures such as tombs, mounds, and temples, oftentimes focusing on structures that were monumental in scale. Works by Bennett (1931), Emory (1924, 1928, 1933, 1934), and McAllister (1933) began to investigate the form of monumental architecture, most notably Hawaiian *heiau* and French Polynesian *marae*, as an avenue to understand migration and colonization patterns in Eastern Polynesia. Emory's (1933) typology of Society Island *marae* defined three "types" of *marae (*Inland, Coastal, Leeward Island). Utilizing chiefly genealogies, and trait lists of various temple types such as Hawaiian *heiau* and Tuamotuan and Tahitian *marae*, Emory developed a relative chronology of Society Island temple types. He argued that inland types with coral faced *ahu* (altars) developed into megalithic Leeward types and Coastal types, where the size of the structure was enlarged and the architectural components were elaborated (Emory 1933: 40). In Western Polynesia, McKern (1929) began to classify Tongan monumental architecture and identified its relative homogeneity across the entire archipelago. In effect researchers were using monumental architecture as a *fossil directeur* to postulate about movements of people and ideas and to track culture change.

Monumental Architecture in Precontact Polynesia, Fig. 3 (continued)

Monumental Architecture in Precontact Polynesia, Fig. 3 Some forms of monumental architecture found in Eastern Polynesia: (**a**) *Marae*/*ahu*, Society Islands; (**b**) Council meeting platform, Society Islands, (**c**) Shrine, Society Islands, (**d**) Fort, Rapa, Austral Islands. (Modified from Anderson and Kennett 2012)

From the 1950s onward, radiocarbon dating ushered in a new period of Polynesian archaeology, one dominated by culture historical questions. Few monumental sites such as temples or tombs were excavated at this time. Yet, the focus on dating coastal middens and rockshelter sites and investigating change through time in artifact form and function had important implications for later studies of monumental architecture. Suggs's (1961) holistic research in the Marquesas Islands began to model how monumental stone architecture, such as *me*'*ae*, stone house platforms, and ridgetop forts, changed through time and began to relate these architectural changes to human demography and island ecology. Green's settlement pattern study in the 'Opunohu Valley, Society Islands, recorded an impressive 136 sites regarded as *marae* or shrines (Green et al. 1967, Table 13). Green excavated three monumental temple structures in the 'Opunohu, using his results to assess and revise Emory's (1933) hypothetical chronology of *marae* development. Green divided Inland *marae* into six subtypes, defined on the specifics of *ahu* form and "decorative

treatment" of the *ahu* (Green et al. 1967: 141). Perhaps most influential was Green's theory that "social differentiation and stratification" which had developed by the eighteenth century were greatly effecting settlement patterns and monumental construction patterns in ancient Tahitian society (Green et al. 1967: 162–163). Such social analyses paved the way for comparative studies of monumental architecture in Polynesian chiefdoms focused on chiefly rank and power.

In the 1960s and 1970s, processual archaeologists in Polynesia widely adopted the settlement pattern approach, a perspective which lent itself to a focus on monumental architecture. Field-based studies began to refine functional types of monumental sites in an attempt to increase archaeological understandings of site use (Kirch 1988). Analyzing the role of monumental architecture in Polynesia likewise emerged as a research goal, often in conjunction with exploring the political and ideological power of elites (Earle 1991). In effect, researchers began using such structures as a proxy for prestige rivalry and elite power, namely, as visual symbols of chiefly authority and hegemony (Burley 1994, 1996; Green 1993; Kirch 1990, 1991). Others stressed how chiefly control over the economy could be articulated through ideology and religious authority at megalithic ceremonial sites (Kolb 1994a, b). Keeping in line with processual archaeologists interest in evolutionary change, Polynesian archaeologists applied the study of monumental architecture to understanding the levels of sociopolitical complexity reached in different Polynesian chiefdoms, whether simple or complex or traditional, open, and complex (see Earle 1991; Kirch 1984) in addition to exploring other questions of evolutionary change (Graves and Ladefoged 1995). Efforts to seriate *marae* and other forms of monumental architecture reflected increased attention to chronology building, in part to refine our understanding of the function of Polynesian monumental architecture (Cochrane 1998, 2002; Graves and Cachola Abad 1996).

In the 1990s some archaeologists in Polynesia began to question the notion that monumental architecture was purely a representation of chiefly economic, political, and ideological power. Studies began to explore how monumental architecture, such as New Zealand *pa*, could serve as symbolic places, markers of territoriality, and loci of group identity (Barber 1996). This trend followed earlier critiques of Polynesian sociopolitical organization that had explored structural and cosmological aspects of Polynesian settlement patterns (Sutton 1990; Weisler and Kirch 1985). The timing of monumental site construction and its relationship to social dynamics, such as collective action, political tensions, and the need to develop, maintain, and strengthen allegiances, became new foci of research (Kolb 2006; McCoy et al. 2011; Wallin and Martinsson-Wallin 2011). Studies began to investigate monumental architecture as aspects of both sacred landscapes and social hierarchies (Campbell 2002, 2006; Kahn and Kirch 2011; McIvor 2015). Recent works have focused on Polynesian monumental architecture as having strategic social value, embodying cosmological principles and world views, creating landscapes encoded in social memories, and reconfiguring human experiences by creating a sense of place (Hamilton 2016; Hamilton et al. 2008; Martisson-Wallin 2014; Richards et al. 2011). Others have explored monumental architecture as territorial displays or costly signals that marked important natural resources (DiNapoli et al. 2019). Finally, some recent studies have stressed the linkage between ritual authority, political power, and monumental architecture, arguing that ritual actions legitimated hierarchical structures broadly within communities and regions rather than just supporting the individualistic power of particular chiefs (Kahn 2016b; Kahn and Kirch 2014; Quintus and Clark 2019).

Current Studies: A Diversity of Methodological and Theoretical Perspectives

Current research on monumental architecture in Polynesia is characterized by a diversity of methodological and theoretical approaches. Methodological debates focus on long held questions of how site form relates to function and the timing and pace of monumental architecture construction. Theoretical perspectives are diverse,

ranging from those applying Marxist-inspired perspectives to monumental architecture, ideology, and chiefly power, to evolutionary approaches exploring phylogeny and historic connections between Polynesian societies, and to social perspectives focusing on the built environment as the creation of places imbued with social memory. Below I briefly introduce some methodological and theoretical topics of continued debate in the region. While the list is not exhaustive, my goal is to give the reader a taste of the current flavors dominating monumental architectural studies in Polynesia.

Methodological Advances and Site Identification: GIS and LiDAR

As with global archaeology, GIS and varied remote sensing techniques have revolutionized field surveys and interpretations of monumental architecture in the Pacific Islands (McCoy 2017; McCoy and Ladefoged 2009). While archaeologists in the region have utilized aerial images for some time in field surveys, commercial satellite images have allowed for the detection of monumental structures and the sites connecting them, as with Easter Island *moai* statues and transportation roads (Lipo and Hunt 2005; McCoy 2018). LiDAR has been used in Tonga and Samoa to identify complete cultural landscapes, including monumental architecture such as burial mounds; star mounds; other mounds of unspecified function, ditch, terrace, and embankment features; and hilltop forts (Fig. 4) (Cochrane and Mills 2018; Freeland et al. 2016; Jackmond et al. 2018; Quintus et al. 2015, 2017). As Freeland and colleagues have noted (2016), the ability to study full cultural landscapes and the monuments therein will refine our understanding of Tongan prehistory, notably in assessing labor requirements needed for constructing massive chiefly mounds versus constructing subsidiary mounds. In addition, the development of regional databases, such as the Samoa Archaeological Geospatial Database combining spatial and temporal data into a single searchable database format, has and will continue to facilitate regional scale analyses of monumental architecture (Morrison et al. 2018).

Methodological Advances and Site Chronologies: AMS 14C Dating, U-TH Dating, and Phylogenetic Analysis

While there is broad acceptance that Polynesian built landscapes, with their diverse forms of monumental architecture, represent palimpsests of construction and use through time, we still lack adequate chronometric datasets needed to refine our temporal scales of analysis in many regions (Flexner 2014; Kahn 2011; Morrison and O'Connor 2018; Mulrooney 2012). Certainly the availability of larger 14C datasets, many of which have good representation of AMS dates on short-lived materials, has allowed for more sophisticated temporal analyses (Kahn 2011; Kahn and Kirch 2011, 2014; Kirch 2010: 160–162; Kolb 2006; Wallin et al. 2007). Some studies have coupled chronometric analysis with seriation of temple types in order to look at long-term sequences of change in monumental architecture and its relationship to the political economy and centralization of elite power (Kahn and Kirch 2014; McCoy et al. 2011; see also Mulrooney and Ladefoged 2005). High-precision ^{230}Th/U dating of corals used in architectural elements or as offerings on monumental sites has revolutioned temporal chronologies in the Hawaiian Islands and Society Islands (Kirch and Sharp 2005; Kirch et al. 2015; Sharp et al. 2010). These data have forced archaeologists in Eastern Polynesia to ponder the rapid imposition of ritual control systems and to rethink models concerning tempos of cultural change.

Finally, similarities in Polynesian ritual architecture have long been used to study cultural phylogenies and culturally shared traits (Kirch and Green 1987, 2001). Cochrane (2015, see also 1998) has expanded on this theme, using cladistic analysis to quantify patterns of relative phylogenetic similarity in Polynesian ritual architecture. No clear phylogenetic patterns or specific lineages of cultural transmission were found, suggesting either high rates of innovation in monumental ritual architecture and a great deal of cultural sharing or horizontal trait transmission. Likewise, Molle's (2016) more traditional taxonomic classification of Tuamotuan *marae* was completed as a first step toward the analysis of

Monumental Architecture in Precontact Polynesia, Fig. 4 LiDAR image with large platforms highlighted, Maninoa and Siumu Village, Upolu Island, Samoa. (Courtesy of Greg Jackmond and Center for Samoan Studies)

historic developments in the region. His study of shared temple names documented widespread *marae* networks across the archipelago. Certainly as regional databases of temples and monumental architecture proliferate, the ability to carry out more computational-based analyses, such as social network analysis, will grow.

Cultural Structuring of Space

Since Weisler and Kirch's seminal article (1985) on Kawela, Moloka'i settlement patterns in the Hawaiian Islands, archaeologists have been attune to the cultural logic embedded in Polynesian landscape use and monumental architecture therein. In a recent Samoan case study, Quintus and Clark (2016) identified large terrace and ditch features in spatially prominent contexts as chiefly residences and sacred open spaces (*malae*). Across such landscapes, they found that Samoan spatial logic was expressed as seaward/leeward and center/periphery dichotomies. One exception was the spatial location of star mounds, which the authors identify as liminal sacred spaces where "individuals could usurp, or at least challenge, the power of leaders"(Quintus and Clark 2016: 11). Other regional Samoan settlement pattern analyses confirm the unique spatial location of star mounds at high elevation points on ridgetops, supporting their specialized function (Morrison et al. 2018). While a different sort of monument, the *Are Metua* or the parent road of Rarotonga, Cook Islands, served as a prehistoric circuit road

structuring the daily movement of people within the broader landscape of residences and ritual structures (*marae*), including "living marae" with ongoing use by descendant communities (Campbell 2006; Downes et al. 2017). A particularly innovative variation on the theme of cultural landscapes is the study of the orientation of Polynesian monumental architecture. Recent works have argued that the layout of some Eastern Polynesian temples, and other monumental structures was organized to align to sacred natural features on the landscape (mountains, cardinal direction, etc.), as well as important celestial events (such as the rising of Pleiades) (Edwards and Belmonte 2004; Kirch 2004a, b; Kirch et al. 2013; Ruggles 2001). Such studies share much with trends in social archaeology that broadly strive to place built landscapes into holistic cultural contexts.

Monumental Architecture as Collective Labor and Community Identity

Along with the notion of changing architectural form, archaeologists in Polynesia continue to be interested in the size and scale of monumental architecture as a means of assessing community labor inputs and exploring collective identities and territoriality (Ladefoged and Graves 2006; Kolb and Snead 1997; Kirch 2010: 156–159; Shepardson 2005). In a comparative Pacific/Mediterranean Island study, Kolb examined the labor necessary to construct and/or transport materials of Rapa Nui *moai* and their constituent *ahu* versus the staged construction of massive Hawaiian *heiau*. He argued that productive circumscription and social competition influenced the rise and use of monumental construction on islands. In a Hawaiian case study, Kirch (2010) utilized rank size distributions of monumental *heiau* (temples) to define specific types (i.e., those for fertility and crop production versus those for war). These data were explored to investigate methods of chiefly ideological control, regulation of tribute, and definition of territorial boundaries.

In terms of community identity, Dixon et al. (1995) provided an exploration of intra- and inter-island political domination in Hawaiian precontact history. Surface mapping of *heiau* on Lana'i demonstrated the hegemonic influence of Maui and the eventual subjugation of Lana'i under Maui rule. In a related manner, Martinsson-Wallin and Wallin (2014) argued that Easter Island *moai* served as symbolic capital materializing competition between junior and senior lineages in the built environment, in effect visually marking tensions between local groups and community level districts.

Other studies have taken a more emic approach to exploring monumental architecture and community identity. Utilizing a house society perspective, Kahn and Kirch (2014) argued that early investments in the landed estate (including elaborate residences) and the ritual estate (including monumental temples and shrines) established access to the corporate estate's natural resources in the Society Islands. Conte and Dennison's analysis (2009) of a Tuamotuan *marae* also took an innovative approach, exploring aspects of intentionally "forgotten histories" in a community's memory. At marae Te Tahata, a series of shallow skeletal burials dated to 1850 when major European-introduced epidemics had devastating effects on Tuamotuan communities. Because these deaths resulted from violent encounters, voluntary silences were reinforced, as traditional *tapu* (taboo) notions of not speaking of the dead were followed so as to protect the living. The chaotic nature of the postcontact period also weakened avenues for the transmission of traditional knowledge, leaving the *marae* and its use as a burial ground part of "forgotten histories." Whether exploring status negotiations, political conflicts, or the effects of European contact, current monumental architecture studies in Polynesian highlight how such sites provide contexts for studying varied social processes.

Relationships to Socioeconomic and Ritual Power of Ruling Elites

For the large part, recent studies of Polynesian monumental architecture largely take economic-ideological approaches. Data are often interpreted through a materialist lens, similar to works in other regions such as DeMarrais et al.'s seminal article on Ideology, Materialization, and Power Strategies (1996). A number of scholars argue

that Polynesian monumental architecture played a pivotal role in supporting ritual authority and oftentimes led to centralized elite sociopolitical power, particularly in the most complex chiefdoms and archaic states (Clark and Reepmeyer 2014; Clark and Martinsson-Wallin 2007; Maric 2016; McCoy et al. 2011; Kahn 2016b; Kahn and Kirch 2014; Kirch 2010; Kikiloi 2012; Kolb 2006). Yet in many regions, baseline survey and additional excavation need to be carried out. As McCoy and Nees (2014: 27) have argued, we need to understand "the organizational principles and beliefs manifested in Polynesian religious architecture" and to refine our knowledge concerning the function and meaning of particular monuments. Below I discuss current ceremonial center-based research in the two archaic states found in the region (Hawaiians Islands, Tonga), as well as research carried out in the most complex of Eastern Polynesian chiefdoms (Society Islands).

The last decade of Polynesian monumental archaeology research has seen sustained interest in investigating chiefly centers and economic control over resources and tribute (Fig. 5) (Kahn in press). In the Hawaiian Islands, temples were hierarchically organized, with each district having its own war temple (Kirch 2010: 60). Kirch (2010: 50) points toward the existence of Hawaiian chiefly centers and royal centers with large domestic sites adjacent to temples as characteristics of the Ku and Lono state religion (see also Cordy 2000; Kolb 1991, 1999). Hinterland regions like Kahikinui, Maui, also saw a rapid imposition of the temple system in the mid-sixteenth century during a period of unification and consolidation (Kirch 2010: 157–165; Kolb 1994a). Interestingly, Hommon's analysis of temples associated with high ranking Hawaiian chiefs argued that late eighteenth-century political centralization saw a de-emphasis on monumental architecture, although he argued that such sites were essential to the aggrandizement of earlier chiefs (Hommon 2013: 248–249, Table 15.6).

In terms of the spatial layout of royal centers, McCoy (2018) recently used LiDAR- and GIS-based data to examine landform and monumental architecture at several centers in the Kona District of Hawai'i Island. By estimating the amount of area available for gathering communities and crowds, McCoy hypothesized that political leaders tried to artificially elevate the density of crowds at low-turnout events while at the same time leaving enough room to accommodate high-turnout events. In a GIS analysis of Hawai'i Island *heiau* viewsheds, Phillips et al. (2015) illustrated that Leeward Kohala Field System temples had more expansive viewsheds through time (see also McCoy et al. 2011). They argued that *heiau* were constructed to ensure place-based agricultural fertility, as well as to extend their visibility into adjacent political districts, thereby reinforcing connections between ideology, chiefly authority, and resource management. A similar Oahu-based analysis concluded that the elevated positions of *luakini heiau* afforded expansive views over surrounding landscapes, situating such temples as highly visible symbols of both political power and chiefly ritual authority (Lyman 2012). Such studies emphasize the multifunctionality of Hawaiian monumental architecture, most notably their engagement in economic, ideological, and political spheres.

Recent analyses of monumental architecture in the Tongan archaic state likewise have emphasized the role of chiefly centers in the development of centralized authority. Lapaha, a political center in the southern portion of the group, comprises a central place covering more than 50 ha replete with royal chiefly tombs, ditch systems, earthen burial and sitting platforms, bathing wells, a canoe harbor, and a wharf (Fig. 6) (Clark et al. 2008; Kirch 1984). The Lapaha tombs represent a dramatic increase in size when compared to tombs at the earlier chiefly center of Heketa, with some of the most elaborate Lapaha tombs representing "energy-expensive structures" (Clark et al. 2016). Major landscape transformations, including land reclamation to build a wharf for double-hulled canoes and construction of a water-filled ditch to demarcate this sacred space, likewise speak to transformations of social space and chiefly authority (Clark et al. 2008). Clark (2015) argued that the specialized nature of the Lapaha center, focused almost exclusively on royal tombs, as well as the tombs' massive size, served as highly

Monumental Architecture in Precontact Polynesia, Fig. 5 Plan view of a Tongan chiefly center, Lapaha. (Modified from Clark et al. 2016)

Monumental Architecture in Precontact Polynesia, Fig. 6 Distribution of chiefly centers in the Hawaiian Islands. (Modified from McCoy 2018)

visual symbols of power and authority, in effect transmitting the semidivine nature of the Lapaha chiefs to the surrounding community. High frequencies of nonlocal stone tools at Lapaha likewise speak to how Tongan chiefs maintained a centralized political system dependent on long-distance canoe voyaging and amassing goods (Clark et al. 2014). Archaeological dating programs demonstrate that rapid site construction sequences at Lapaha emerged during a period of increasing political centralization and chiefly economic power (Clark et al. 2008, 2014).

While more limited in scope, studies in the Society Islands, the most complex of Eastern Polynesian chiefdoms, have likewise suggested correlations between the centralization of elite political and socio-ritual power and the construction of primary and secondary ritual-political centers. Maric's (2016) analysis of Ma'ohi oral traditions emphasized how chiefs asserted divine right through marriage alliances with the "royal" Tamatoa lineage from 'Opoa on Ra'iatea, whose leading elites presided at the chiefly center of Taputapuatea (Fig. 7). While "royal" *marae* were constructed as early as the fifteenth century, in the seventeenth to eighteenth centuries a new war cult dedicated to the god 'Oro saw the construction of larger and more elaborate chiefly centers on coastal promontories (Kahn and Kirch 2014; Maric 2016; Sharp et al. 2010; Wallin 2014). These new ceremonial centers had similar site types and reproduced much of the same spatial layout as the original Taputapuatea ceremonial complex (Ra'iatea Island) (see Kahn in press), considered to be the first ceremonial center dedicated to the 'Oro war cult. Like the Hawaiian and Tongan examples, the elaboration of Mā'ohi chiefly centers occurred rapidly within a context of increasing centralization of elite power. By the seventeenth century, chiefs increasingly controlled surplus agricultural production which was funneled up to elites as tribute at ceremonial centers with megalithic *marae* and a range of socio-ritual specialist structures (i.e., meeting houses, council meeting platforms, archery platforms) that were often monumental in their size and architectural elaboration (Kahn and Kirch 2011, 2014; Lepofsky and Kahn 2011).

Related research on minor ritual-political centers has also augmented our understanding of how secondary chiefs deployed the construction and use of monumental architecture, and the ceremonies carried out therein, in power building strategies. Inland aggregate ritual centers were increasingly constructed by competing Mā'ohi junior elites (i.e., secondary chiefs) from the seventeenth century onward (Fig. 8) (Kahn 2011; Kahn and Kirch 2014). Such bounded ritual zones allowed junior elites to manipulate local

Monumental Architecture in Precontact Polynesia, Fig. 7 Plan view of Taputapuatea chiefly center, ʻOpoa, Raʻiatea, Society Islands

political economies and integrate community-based economic practices within the regional ritual calendar, just as primary centers afforded the most high ranking chiefs avenues for establishing, maintaining, and expanding their sociopolitical, economic, and religious power (Kahn in press). Yet these secondary centers also offered junior elites access to the performative and intermeshed power of ritual, sport, feasting, and gift exchange. Such social practices both buttressed the specific roles of junior elites within regional hierarchies and provided opportunities for negotiating and contesting the contingent forces of *mana* (sacred power) at multiple scales within the hierarchy, namely, between and among chiefs and secondary chiefs, chiefs and *raʻatira*, and elites versus commoners (Kahn in press).

Concluding Thoughts

While Polynesian monumental architecture studies are both broad and dynamic in terms of archaeological method and theory, I end with some brief thoughts for how the field might move forward. Currently, there is no singular accepted definition of monumental architecture in the region. Researchers utilizing economic models tend to emphasize monument size, while those utilizing socially informed landscape models tend to emphasize site context and site proxemics. While this is not inherently problematic, it does pose the question: what was the meaning of such structures to the Polynesians themselves? Further research into site place names (toponyms) and their role in the rich corpus of Polynesian

Monumental Architecture in Precontact Polynesia, Fig. 8 Plan view of the ScMo-129-161-163 secondary chiefly center, ‘Opunohu Valley, Society Islands

precontact myths and legends may help to tease out such emic views. Secondly, for a region that has had a long history of comparative archaeological research, there have been few recent efforts to synthesize Polynesian monumental architecture from a regional point of view, where monuments from one cultural group are compared to another (but see Cochrane 2015; Kolb 2012). Certainly, in one sense, the lack of comparative work continues due to the paucity of foundational data. For example, some archipelagoes in Central Eastern Polynesia, such as the Austral Islands and the Gambier Islands, lack detailed inventory survey data, while most Central Eastern Polynesian archipelagoes, such as the Tuamotus, Marquesas, Gambiers, and Australs, have limited chronological data on monumental sites. Unfortunately, the pace of modern development is negatively impacting Polynesian monumental structures in many locales; on the whole regional preservation rules are not strong enough, nor is there monetary support to enforce them. As such, archaeologists should prioritize community-based projects focused on specific monuments or regions that weigh heavily in particular community's minds. If not, the oral traditions and early survey work of the first half of the twentieth century might be the only lasting traces of these dynamic structures that remain for Polynesian communities in the long term. As archipelago-wide datasets expand and become more available, comparative studies relating island isolation, natural resources, and level of social complexity should incorporate comparative analyses of monumental architecture to investigate how factors such as isolation and social circumscription relate to sociopolitical and economic expressions of authority.

Morgan, Jeff

Jeff Morgan
Global Heritage Fund, Palo Alto, CA, USA

Basic Biographical Information

Jeff Morgan is a trained city and regional planner, earning a B.S. from Cornell University. He received an M.S. in Management from Stanford University's Graduate School of Business.

Major Accomplishments

Jeff Morgan is the executive director of the Global Heritage Fund (GHF), a position he has held since founding the organization in 2002. He is a member of the Global Heritage Fund's Senior Advisory Board and the Board of Trustees. In the position of executive director at GHF, he is responsible for global conservation excellence, building a leading international conservancy and improving the lives in communities where GHF sites are located. He also serves on the Stanford Institute for Economic Policy Research Advisory Board.

Morwood, Michael

Andrew Thomas Wilkinson
College of Humanities, Arts and Social Sciences, Flinders University, Adelaide, SA, Australia

Basic Biographical Information

Michael (Mike) Morwood (Fig. 1) was awarded his B.A. in Archaeology at Auckland University, New Zealand, in 1973, receiving his Masters in the following year. In 1972 the Auckland University Department of Anthropology awarded Morwood the Anthropology Prize for academic excellence. Morwood commenced further graduate studies in 1976 at the Australian National University. He was awarded his Ph.D. in 1980. His dissertation was titled *Art and Stone: Towards a Prehistory of Central-Western Queensland* (Mike Morwood 2010).

Morwood began his career employed as regional archaeologist by the Queensland State Archaeology Branch of the Department of Aboriginal and Islander Affairs (DAIA) between 1974 and 1976. After receiving his doctorate, he returned to the DAIA in Queensland as a field and research archaeologist. In 1981 he began lecturing at the University of New England. As a part of the School of Human Environmental Studies, Morwood lectured in Australian archaeology, Southeast Asian and Pacific archaeology, rock art, archaeological field methods, and archaeological lab methods. It was during this time he discovered *Homo floresiensis*, a hominin species that "...prompted reassessment of fundamental tenets in palaeoanthropology...concerning the peripheral role of Asia in early hominin evolution" (Professor Michael "Mike" Morwood 2011). Morwood moved to Wollongong University in 2007 where he is currently a professor at the School of Earth and Environmental Studies. His research interests include archaeology of Southeast Asia and Australia, early hominin evolution and dispersals, origins of modern humans, rock art, Southeast Asian biogeography, and ethno-archaeology.

Mike Morwood was elected President of the Australian Rock Art Research Association in 1992, a position he held until 2000. In 2003, Morwood was elected a Fellow of the Australian Academy of the Humanities, an organization dedicated to the advancement of knowledge in humanities. Other professional positions he has held include Professorial Fellow Archaeology in the School of Earth and Environmental Studies at the University of Wollongong between 2007 and 2009, Adjunct Professorial Fellow at the University of Western Australia between 2009 and 2010, Adjunct Professorial Fellow at the University of New England from 2009, Adjunct Professorial Fellow at Charles Darwin University from 2009, and Adjunct Professorial Fellow at Padjadjaran University, Bandung, from 2010.

Major Accomplishments

Models for the early hominin dispersal out of Africa received considerable attention when the

Morwood, Michael, Fig. 1 Mike Morwood in the field in Sulawesi, Indonesia

joint Australian-Indonesian research team headed by Professor Morwood discovered *Homo floresiensis* in the Liang Bua cave on the Island of Flores, Indonesia (Morwood and Oosterzee 2007). The finding of *Homo floresiensis*, released on the 28 October 2004, has implications for the dispersal of hominin and human dispersal out of Africa and the colonization of Asia. It has attracted substantial debate from, in part, supporters of the multiregionalist theory of *Homo sapiens* evolution (Morwood). The continued study of *Homo floresiensis* has taken a multidisciplinary approach including paleoanthropological, morphological (see Kaifu et al. 2011), and pathological analysis combined with dentition study, ancient DNA extraction, and tomographical techniques. Of additional interest to the find are the lithic tools associated with the discovery of *Homo floresiensis* and the cognitive behaviors connected with their manufacture and use (Brumm et al. 2006). Recent research estimates the faunal sequence and minimum age for hominins on Flores at 1.1 million years ago, ensuring the study covers the entire period of hominin habitation in the region. Excavations at Mata Menge, Flores, hope to provide greater evidence on the early hominin colonization of the Indonesian area. The public interest in these hominin finds has sparked numerous documentaries and written works detailing all manner of scientific investigation and discussion on the subject.

More recent multinational research projects have identified the interactions of human activity, the local environment, climates, and island faunas in long-term changes in Indonesia. The implications for island biogeography and evolution can be seen extending throughout significant periods of time. A collaborative project, with funding from the Australian Research Council, involving Indigenous communities, the University of New England, the Australian National University, the W.A. Department of Environment and Conservation, the Kimberley Foundation, and Heliwork, is looking at the complex cultural sequences resulting from human occupation and the impacts on faunal habitation through investigating the distribution, chronology, and subject matter of cultural heritage sites. The research being conducted

in the Kimberly region of Australia may provide evidence of the effect of environmental and cultural alteration as a result of climate change and human habitation in the area (Professor Michael "Mike" Morwood 2011).

Mike Morwood's innovations in on-site field data recovery include the adaptation of shoring techniques found on industrial construction sites that are well suited for deep excavations. In addition, Morwood developed effective wet-sieving techniques that greatly improved finds recovery from excavated material. He is known for his use of an intelligent database design for recording excavated materials and the documentation of site contexts. His experience in directing large-scale projects has ensured the success of collaborative projects between local government agencies, research centers, and interdisciplinary organizations, both in Australia and Indonesia.

As a globally recognized scholar, Mike Morwood is known for his interdisciplinary projects that have embraced various media avenues to promote archaeology to the public. His publications communicate the excitement of archaeological discovery to a wider audience. His scientific research encourages the use of high-profile discoveries to promote archaeology. He is also recognized for his enthusiastic and high-quality training of students and postdoctoral scholars. His former students hold high-level government posts, business and academic positions throughout Australia and in other countries where he has conducted research. Mike Morwood died in July, 2013 in Darwin, Australia.

M

Mosaics: Conservation and Preservation

John Stewart
English Heritage, London, UK

Introduction

Conservation is the process of preserving cultural heritage for the benefit of future generations. Mosaics present particular challenges, whether

in situ on archaeological sites or within museum collections.

Definition

Mosaics in the Classical tradition consist of a surface of small cut cubes (*tesserae*) of stone, ceramic, or glass (forming the *tessellatum*), often in a decorative configuration. This is the visible part of a composite structure, with a support of multiple levels of lime mortar and a stone rubble base, many times thicker than the *tessellatum* itself. The Latin nomenclature for these different layers is known from the writings of the Roman architect Vitruvius. In Roman architecture, the vast majority of mosaics were floor pavements, but they also embellished walls and vaults as well. In other cultures, different materials may be found. The reference in this entry is to Hellenistic/Roman/Byzantine mosaics.

The origin of Classical mosaics is in the Hellenistic pebble pavements of the eastern Mediterranean. They formed an integral part of much Roman architecture throughout the Empire and endured through the Umayyad and Byzantine periods.

Conservation of mosaics entails numerous activities, such as modification of their environment to mitigate the causes of deterioration or restoration of their structural stability through the addition of new materials.

Key Issues/Current Debates/Future Directions/Examples

Historical Legacy

European interest in Classical antiquity in the Renaissance was invigorated by the discovery of Pompeii and Herculaneum in the mid-eighteenth century.

Early interventions involved the lifting of selective parts of mosaics, usually the highly prized figurative *emblemmata* (central panel), to be displayed in antiquarian collections much as paintings. Presumably, those of lesser interest were abandoned. The detached *tessellatum* was reset onto a new mortar bed of lime mortar or gypsum (or cement mortar from the nineteenth century), fixed to a sturdy support such as wood or stone slate. Restoration of the decorative pattern of the *tessellatum* often utilized loose *tesserae* from the excavation, with a degree of speculation depending on the extent of its preservation. Mortar grouting was then applied into the joints between *tesserae*, followed by mechanical abrasion of the surface to achieve a smooth and polished finish. This effaced differences between the authentic and restored artifact. Wax was often applied to mosaics exposed indoors to enhance color contrast; it darkened over time.

The first tentative attempts at the preservation mosaics in situ occurred from the late eighteenth century. In central Europe, this sometimes entailed the erection of simple vernacular structures over mosaics to protect them from inclement weather and vandalism.

Surviving mosaics, either lifted or conserved in situ, constitute a fraction of those discovered and either willfully destroyed or lost through neglect.

The removal of mosaics to museums was intended as an act of preservation. However, this was by no means guaranteed, and countless lifted mosaics have perished either in site stores or in museums, particularly if they were never reset on a solid new mortar support.

The most unwitting damage sustained by treated mosaics is through the use of artificial Portland cement mortars, progressively developed over the nineteenth century and employed exclusively in many countries through the twentieth century (see below). This was further exacerbated by the introduction of reinforced iron into new cement mortar supports in the twentieth century.

In the last quarter of the twentieth century, a greater appreciation for the value of mosaics in their authentic architectural context focused energies on their conservation in situ. Throughout Europe, protective cover buildings were erected over many structures containing mosaics. Revival of the use of traditional lime mortars for building

conservation was beneficial for mosaics as well, in reaction to the damage inflicted by mortars based on cement.

Better technical interventions such as these have not been sufficient to address the general crisis in the conservation of mosaics on archaeological sites, as a result of poor management. Loss of this heritage is progressive, relentless, and immeasurable.

Deterioration and Damage

Ancient Damage

Any pavement is subject to physical abrasion and impact damage within an occupied building. Indeed, ancient repairs to mosaics are frequently encountered. Disasters such as fire or earthquake were also common. With eventual abandonment, mosaics were buried through a combination of building collapse and site erosion.

Buried Mosaics

In a burial environment, the constituent materials of mosaics (stone, ceramic, and mortar) sustain much slower rates of deterioration than in an exposed one, with large variations in temperature and moisture content. This accounts for the intrinsic survival of so many ancient mosaics. However, some damage may occur from tree roots, burrowing animals, and weak inorganic acids in soil; the latter may leach out calcium carbonate from mortar, resulting in a friable matrix without binding power. In contrast, thin "veils" of calcium often precipitate onto the surfaces of mosaics in burial conditions; these cause no physical harm but do obscure the surface.

Exposed Mosaics In Situ

Upon excavation, all archaeological features undergo a physical "shock" through exposure to a more dynamic ambient environment in which physical and chemical processes interact to degrade materials. The rate of deterioration depends on several factors, intrinsic to the materials of the mosaic, its physical history, and the aggressiveness of its new environment.

Inherent natural faults in its materials, such as *tesserae* of clay-rich sedimentary limestone, may fracture and delaminate in humid conditions. As composite structures, mosaics have multiple planes of weakness, which offer preferential paths for root penetration or detachment of different horizontal layers from differential dimensional change. Ancient mortar, which has degraded in burial conditions (see above), results in a loss of physical integrity of the composite structure, including the large-scale detachment of *tesserae*.

Low forms of plant life (such as moss) lead to the colonization by higher plants, whose root structures can destroy entire pavements. Another potentially aggressive form of environmental degradation is from soluble salts in the soil. Dissolved in groundwater, these migrate into a mosaic structure through capillary forces; in dry ambient conditions, they crystallize and expand within the pore structure of stone, ceramic, or mortar near the surface. Certain compound salts increase many times in volume upon crystallization and eventually destroy such porous materials. A powdery material is the result.

Inappropriate Interventions

The use of cement mortars, and iron-reinforced cement supports, has been the most harmful form of intervention. Cement is an impervious material with high soluble salt content, concentrating moisture movement, and associated decay in the ancient fabric; furthermore, it is very difficult, if not impossible to completely remove. Where iron reinforcement is present in external or damp internal environments, moisture penetrates through micro-fissures and cracks, causing the corrosion and expansion of the iron and fracturing of the mosaic itself. Gradual loss of alkalinity of the cement also results in iron corrosion.

The process of lifting and relaying of the *tessellatum* on a new mortar support results in a loss of material authenticity and integrity, as the ancient bedding layers which contain much technological information are destroyed; relaying also normally creates an aesthetically bland, flat surface, particularly if cement is used. A common finishing

technique was (and still is in some countries) the physical abrasion of the surface of the *tessellatum* to remove any lime concretion and thus enhance the overall design of the mosaic. This further compromises archaeological integrity.

Storage and Presentation Environments

The damage from damp storage environments has been cited above. Storage facilities designed without regard to potential risks can be subject to flooding, fire, or theft. Museum buildings with damp problems can also cause damage to mosaics presented on floors or mounted on walls.

Modern cover buildings erected over mosaics in situ are sometimes designed without an adequate understanding of the condition of sheltered mosaics and the attendant risk environment. This means they either fail to protect from obvious environmental factors (such as site hydrology) or they create an internal environment which accelerates damage from natural processes (as crystallization of soluble salts).

Lack of Maintenance

Poor or nonexistent maintenance is the principal cause of deterioration of mosaics in situ in exposed environments. Poor maintenance is a direct result of incompetent or ineffective management structures and poor training and not necessarily the lack of sufficient financial resources.

Assessment

Any conservation intervention should be preceded by an assessment of a number of factors:

- Significance of the mosaic: cultural importance (in terms of materials, iconography, and craftsmanship) within a specific region
- Condition of the mosaic: current physical state of the materials and structure and the cause (s) and rate of deterioration
- Vulnerability of the mosaic within its risk environment: local environmental risks (e.g., soluble salts, flooding)

The assessment of significance should normally be carried out during a preliminary archaeological inventory (e.g., the creation of an academic *corpus* of ancient mosaics for a given region and country). This, in turn, should contribute to the national Sites and Monuments Record, providing unique numerical identities to each mosaic within a GIS matrix.

There are essentially three levels of mosaic condition survey:

- Preliminary or reconnaissance survey: a relatively rapid initial survey to capture basic data about the condition of a large number of mosaics
- Detailed (or conventional) condition survey: a detailed inspection usually for more significant pavements
- Specialist survey: material analysis or geological prospection undertaken for significant pavements at risk

A condition survey considers and records: the context of the mosaic (the natural environment and building structure within which it is contained), the materials and structure of the mosaic, any repairs or interventions, and, finally, the physical manifestations of deterioration and their likely causes. The survey report should provide recommendations for intervention, and prioritization of treatments, based on diagnosis and prognosis.

Conservation Interventions

Good management of collections of mosaics, either in situ or in museums, requires an understanding of their significance, condition, and risk, in order to identify the interventions which will guarantee the most beneficial outcome. Only individuals with the appropriate knowledge, experience, and skill to implement them should undertake any interventions in mosaics.

The care of mosaics in situ is particularly challenging, given the aggressive environmental forces to which these are subject. In order to best preserve the mosaic heritage with finite financial resources, a variety of conservation measures usually need to be implemented, following a prioritized program. This should take into account the

significance and condition of pavements, ease of access, existing or planned visitor interpretation, and available resources:

- Reburial of mosaics not to be presented in the foreseeable future
- Presentation and interpretation of selective mosaics on a planned visitor circuit (with consolidation, maintenance, and monitoring), possibly under cover buildings

Stabilization of Mosaic Context

Erosion of slopes around exposed mosaics deposits soil which promotes vegetation. Slopes can be stabilized by natural or synthetic netting fabricated for this purpose and the planting of indigenous shrubs.

Where such mosaics are in the path of recurrent rain runoff, land drains can be placed in strategic positions to intercept and evacuate water. Site drainage may also help reduce moisture content within a mosaic and consequently growth of microorganisms on it. Modern synthetic "geodrains" are relatively narrow and thus limit the destruction of archaeological stratigraphy for their installation.

Mosaics in situ within unstable or faulty structures (ancient ones or modern cover buildings, museums, stores) are at risk of damage. Also, exposed mosaics on slopes may be undermined by natural erosion. Masonry repairs need to be undertaken to secure perimeter structures and mosaic foundations, possible with enhanced drainage.

Reburial of Mosaics In Situ

Archaeological mosaics have survived due to a burial environment, and the reinstatement of a burial regime can be a very effective conservation option, if well planned. This may be for short periods (e.g., between excavation seasons), for moderate periods (e.g., during planning for a new cover building), or for the long-term periods (where presentation of the pavement is not currently envisaged). Reburial also prevents deterioration from aggressive soluble salts, where these are present.

Effective protection requires the design of a good burial cover (appropriate materials and stratigraphy), perimeter drainage, and maintenance. Intimate contact between the surface and cover medium (usually soil) is essential. Synthetic separation membranes, such as geotextiles are often incorporated into the reburial stratigraphy, to facilitate re-excavation, or provide chronological "markers" to future archaeologists. These are not strictly necessary in conservation terms; they may inhibit the free movement of water in the reburial regime, which can have detrimental consequences, or promote root growth under the membrane.

Cover Buildings or Shelters

Mosaics exposed to the elements in situ will invariably deteriorate at a faster rate than if protected under cover. To be most effective, cover buildings or shelters need to be designed to a very specific brief, addressing the vulnerability of the mosaic and associated environmental hazards.

Consolidation and Stabilization of Mosaics

The vast majority of remedial repairs to mosaics can be carried out with a palette of lime mortars, based on a binder of lime and an aggregate of sand. Lime is of two varieties, dependant on the mineral properties of the parent stone: non-hydraulic lime, which sets in reaction with carbon dioxide in the air, and natural hydraulic lime, which sets additionally through a chemical reaction with water. The former is appropriate for most surface treatments, while the later is necessary for surfaces of mosaics which are persistently damp or for the grouting of voids within mosaics where there is less ambient carbon dioxide available.

Technicians undertaking repairs should be adequately trained in the use of lime mortars, which must be properly specified and applied, if they are not to fail. Cement-based mortars are never appropriate nor gypsum in external environments.

Typical mortar treatments consist of:

- Protective borders around the exposed edges of the *tessellatum* to retain *tesserae* in place
- Filling of deep joints between *tesserae* where original mortar is lost
- Filling of losses in the *tessellatum* to prevent water ponding and growth of vegetation
- Readhesion of loose *tesserae*
- Injection grouting of voids in mortar support layers to prevent collapse or detachment

Mosaics to be presented require additional consideration of the appearance of new mortar. Color and texture of mortars used on the surface are provided by careful selection of the mortar aggregate and finishing treatment.

A less frequent treatment is the consolidation of degraded *tesserae*, usually caused by soluble salts. This is a specialist process using chemical consolidants, undertaken by an experienced conservator. There is no perfect chemical consolidant, and efficacy is limited by residual salts and by external exposure.

Cleaning

Periodic cleaning of mosaics is necessary, particularly in external environments to remove microorganisms or accumulated soil, which encourages plant growth. This is done with clean water and nonionic detergent (which leaves no harmful residual products), applied with soft brushes and sponges. Biocides should be used with caution, as their residual effect is limited and some leave soluble salts in the mosaic as well.

Surface lime concretions should never be removed by aggressive abrasive methods, as this destroys the integrity of the *tessellatum*. Sensitive methods include mechanical removal by scalpel, controlled micro-abrasives, or by chemical means with chelating agents. These are specialist techniques undertaken by or under the close supervision of a qualified conservator.

Surface Coatings

There is often a desire to enhance the design of the *tessellatum* with surface coatings. These all darken with time and attract air-borne particulates and therefore should never be used outdoors. Even if a coating is reversible at the time of application, it may become less so over time, making removal problematic. They are best avoided.

Treatment of Mosaics on Iron-Reinforced Cement

Maintenance Corrosion of iron reinforcement in external environments cannot be prevented, but its rate can be mitigated by systematic maintenance to prevent ingress of liquid water. This means filling all cracks and micro-fissures with suitable mortars.

Storage Detached mosaic panels with iron-reinforced backings should be stored in the driest conditions possible to reduce the rate of corrosion.

Removal of Backing Remedial techniques for the stabilization of reinforced concrete in modern buildings include passivation of iron by means of cathodic protection or sacrificial anode cathodic protection. Unfortunately, this technology is not easily transferable to mosaics on archaeological sites but may be possible inside a museum.

Mosaics in an advanced state of deterioration can only be rescued through the removal of the backing. This is an expensive and laborious exercise, undertaken by conservators with specialist experience, using stone cutting equipment under precision control. The *tessellatum* is secured in advance with multiple layers of natural fabric and reversible adhesive to secure it during this operation.

When most of the cement has been removed, the *tessellatum* is mounted on a new support as described in the section immediately below.

If mosaics in situ contain corroding iron bars near the surface, it may be possible to remove them surgically, after facing the surface with fabric applied with reversible adhesive and filling voids with mortar.

Lifting and Relaying

Current cultural heritage policy endeavors to preserve mosaics in situ, either through reburial or presentation. In some instances, lifting and relaying may be required:

- For very degraded mosaics with large areas of loose *tesserae*
- For mosaics subject to erosion from aggressive soluble salts from the ground
- Where the site is to be destroyed for development

In advance of lifting, the *tessellatum* is rigorously cleaned and stabilized with mortar as necessary. It is then faced with several layers of natural fabric, applied in intimate contact with the surface, with a reversible adhesive. Depending on the size of the pavement and complexity of design of the *tessellatum*, it is either cut into small sections or lifted intact. Metal blades and rammers are used to undercut the mortar support layer, and the each small section of the *tessellatum* is then "sandwiched" and secured between wooden boards for transport away from the site. If the *tessellatum* is to be lifted whole, it is fixed to large wooden drum and rolled as it is undercut; this operation carries greater risk of damage.

Relaying In Situ A mosaic to be reinstated in situ requires a solid new foundation (of hydraulic lime mortar, but cement mortar may be used if not in immediate contact with the *tessellatum*). On sites with high levels of soluble salts and a high water table, a conventional damp-proof course should be inserted into the new mortar foundation. New perimeter drainage should be installed as required.

Degraded bedding mortars are recorded prior to their removal from the back of the *tessellatum*. It is then relayed on the new foundation with lime mortar, the facing is detached and the surface made good with mortar.

Relaying on Panels New solid mounts or supports are required for those mosaics which cannot be returned to their original site. Cement-based materials and iron reinforcement are never appropriate. Instead, best practice utilizes synthetic "honeycomb" boards consisting of an internal matrix of aluminum in honeycomb form, with surfaces of glass fiber in epoxy resin. Being rigid, strong, and lightweight, such panels are ideal supports for detached mosaics. They are fixed to the *tessellatum* with epoxy resin or epoxy foam, with an intermediate "intervention layer" of reversible lime or synthetic mortar.

Such honeycomb panels and epoxies are widely available and affordable in developed countries. Elsewhere, they are expensive and difficult to procure. Research is underway to identify local alternatives.

Maintenance and Monitoring

The preservation of all mosaics, either in situ or in museum collections, requires ongoing care, through maintenance and monitoring of condition. This is the most neglected conservation activity.

Good maintenance requires the creation of maintenance schedules, both for mosaics and their context (site store, museum, or cover building). There are three complementary types of inspection:

- Periodic inspections: on a planned basis at defined intervals
- Occasional inspections: following severe weather or unforeseen events (e.g., floods)
- Cyclical or planned preventive maintenance: at predetermined intervals

Routine tasks consist of vegetation removal (done with care to avoid surface disruption) or treatment with benign herbicides, cleaning of the *tessellatum*, maintenance of protective site barriers, and stabilization of the *tessellatum* with small lime mortar repairs.

Regular monitoring of the condition of mosaics is the responsibility for those who care for them, to ensure that problems are noted as they arise and defects are treated in a timely manner.

Conclusion

The material, aesthetic, and archaeological integrity of most mosaics can be preserved with confidence by the technical means described above. However, this requires both adequate training in

their execution, understanding of their vulnerability, and implementation of a robust management context to guarantee their continued survival.

Moseley, Michael

Patrick Ryan Williams
The Field Museum, Chicago, IL, USA

Basic Biographical Information

Andean archaeologist, member of the National Academy of Sciences, and fellow of the AAAS and Guggenheim, Mike Moseley is known for his research on early South American civilizations,

the intersection between man and his environment, and pioneering work in geoarchaeology. Moseley was educated at Berkeley (BA 1963) and Harvard (PhD 1968).

Born in Dayton, Ohio, to a military family, Moseley moved through Wiesbaden, Germany; Washington, DC; and the Dakotas before landing in southern California as a youth. His talent for archaeology was recognized early as a teenager where he was engaged in field archaeology in the mountain West and Grand Canyon in his early years. After completing his BA and PhD, Moseley taught at Harvard University, University of Chicago, and University of Florida over the course of his career, mentoring dozens of PhD students through the years. During his time in Chicago, he was also Curator of Anthropology at the Field Museum of Natural History.

Major Accomplishments

Moseley's PhD thesis and later book on the maritime foundations of Andean civilization (1974) reconfigured the understandings of the underpinnings of social complexity, arguing that rich marine fisheries as well as agriculture could form the economic base for the rise of complex polities. He later directed the Chan Chan Moche Valley Project (Moseley and Cordy-Collins 1991; Moseley and Day 1982), one of the largest collaborative research programs on urban prehistory ever developed in the Andes. His interest in the environmental foundations of urbanism led him to direct the Proyecto Riego Antiguo (1983) to examine the foundations of Moche irrigation systems. This work propelled his interest in how natural disasters affected human societies and led him to develop several innovative field methodologies in geoarchaeology (Moseley 1997, 2002).

Moseley's interests shifted to the south-central Andes in the late 1970s, where he was instrumental in building research programs at Tiwanaku as advisor to the National Archaeological Institute of Bolivia. Shortly thereafter, he partnered with Peruvian colleagues to establish the Programa Contisuyo based in the Moquegua valley of southern Peru. His and colleagues' discoveries of Tiwanaku and Wari colonies around the site of Cerro Baul propelled research on the earliest expansive states in the Andes in the only area where both maintained long-term colonial projects (2005). The Programa Contisuyo has hosted over one hundred investigators and dozens of research projects over more than 35 years since Moseley founded it. The Programa generated the research and collections base for the Museo Contisuyo, which has been Moseley's seat of investigations in Peru since 1994, as well as being the principal archaeological museum and public outreach center in far southern Peru.

Moseley's work has been truly influential in the generation of archaeological scholars working in the Andes today. He and his students have produced a large number of the professional archaeologists working in South America. His most important publications speak to the modern relevance of his work. From *Maritime Foundations of Andean Civilization* (1974) to *The Incas and Their Ancestors* (1992) to Burning Down the Brewery (2005), he has been a grand synthesizer of the human past.

Mostny, Grete

Andrés Troncoso
Departamento de Antropología, Universidad de Chile, Santiago, Chile

Basic Biographical Information

Grete Mostny Glaser was born on September 14, 1914, in Linz, Austria, but she lived most of her life in Chile. She lived there for about 50 years and became a Chilean citizen in 1946. She died of cancer in Santiago on December 15, 1991.

She studied at the University of Vienna's Faculty of Arts where she earned his first PhD in Egyptology, African Studies and Prehistory. She earned a second PhD at Brussels Free University in Belgium, in Philology and Oriental History with honors in Ancient Orient. Although her PhD dissertation was delivered and passed, her PhDs degree ceremony was not carried out since as it was scheduled for March 15, 1938, and 2 days earlier Hitler had Austria annexed to Germany (Durán 1977, Acevedo 2014).

In 1939, Grete arrived at Valparaíso city in Chile, together with her mother, and met her brother, who was there waiting for them. In Chile, she held a long and prolific career in archaeology, working at the most important State museum: the National Museum of Natural History. She was the Head of the Anthropology Department between 1943 and 1964, and then she was appointed Director, a position she held until 1982. In the 186 years of its existence, this institution had been managed only by two women, and Grete Mostny was the first.

From the moment Grete Mostny arrived, she stood out in the Chilean scientific scene. On the one hand, she was part of a context where archaeology was performed by professionals with university education in fields outside the discipline. On the other hand, her background and contacts with European archaeology allowed her to be a highly qualified counterpart to receive researchers, such as Junius Bird, who carried out works in the Chilean territories.

Grete Mostny residence in Chile, and her position as Director of the National Museum of Natural History led her to experience the violence of oppressive states, this time by the *coup d'etat* deployed by Augusto Pinochet on September 11, 1973, against the democratically elected government of Salvador Allende. Despite the country's political milieu, budget cuts, and the dictatorship's lack of interest in cultural issues, Mostny managed to keep control of the museum management and development, in the process succeeding in remodeling the museum ground floor in order to open a new permanent exhibition.

Throughout her life and after her death, Grete Mostny received a series of distinctions. She was a permanent member of the International Congresses of Prehistoric and Protohistoric Sciences, of the Latin American Association of Museums, of the International Council of Monuments Executive Council, and of the Pan American Institute of Geography and History's Anthropology Committee. In 1949, the University of Cuzco awarded her the *Honoris Causa* PhD. In 1967, the government of Austria gave her a national honor award in Arts and Sciences. In 1977, she was appointed honorary member of the Chilean Society of Archeology. In 2013, the Faculty of History and Cultural Studies of the University of Vienna created the Grete Mostny *Dissertationspreis*, which recognizes the best doctoral theses. In addition, a prize that bears her name is awarded at the National Museum of Natural History's Junior Science Fair, which was created by Grete Mostny in 1970 (Acevedo 2014).

Major Accomplishments

Grete Mostny was a key figure in the development of archaeology in Chile. She was not only the first archaeologist, professional, and scholar, and the first woman to do archaeological research in the country, but also one who made great contributions to the discipline. Mostny developed a prolific body of research on archaeology, ethnography, ethnohistory, and physical anthropology throughout the country that was published in different journals in Chile and abroad. Among her publications, one of the most important is her book *Precolumbian Cultures of Chile* (1954a), later reprinted as *Prehistory of Chile* (1970), which have been reprinted several times. This is one of the few publications that summarize the pre-Hispanic history of the country and accounts for one of Mostny's main concerns: the protection and diffusion of national cultural heritage. Her commitment to heritage and her work in the National Museum of Natural History allowed her to access, recover, and preserve the famous "mummy" of El Plomo Mount. This was the frozen body of a child who was offered and buried in the high Andean peaks of Santiago by the Inka State in the sixteenth century AD. The child was found and dug out by mine surveyors at the top of the hill and then taken to Santiago City. It was due to Grete Mostny's efforts and determination that the child of El Plomo Mount was acquired and preserved by the museum. Today, it is one of the best examples of the Inkas high andean peaks rituals in the south of the Empire. Mostny also developed and published the study of this body, becoming one of the first multidisciplinary works on this subject (Mostny 1957).

This integrated approach to the register is expressed in her work on the Peine region, where she combines the ethnographic, linguistic, bioanthropological, and archaeological work to understand the Atacameña community. This is one of the first investigations that apply ethnoarchaeological perspectives to the study of Andean societies and to rescue ethnographic information for the interpretation of the archaeological record (Mostny 1954b).

A concern for the conservation of, and education about, cultural heritage was central to Grete Mostny's work and legacy, and it left a deep trace in Chile. Through her work at the National Museum of Natural History, she created the National Museology Center (1968), the first of its kind in Latin America directed toward training specialists in the field. She also founded the Museum Conferences

M

(1977) to bring together the Chilean specialists in the field of Museology. She promoted the creation of the Association of Chilean Museums (1959) and the Latin American Association of Museums (1973). In 1967, she founded Chile's Scientific Youth, which later gave way to the Junior Science Fair, designed to promote the practice and teaching of science to schoolchildren. This activity continues to this day bringing together thousands of people in each of its presentations.

"Motif" in the Archaeology of Art

Inés Gordillo
Institute of Archaeology, Faculty of Arts, University of Buenos Aires, Buenos Aires, Argentina

Introduction

The term *motif* is perhaps the most widely used in archaeology art, in both rock art studies and portable art. This is a category of analysis that has dominated the field through all its theoretical and methodological perspectives (Fiore 2009). However, few authors have focused on defining it, often assuming its highly intelligible meaning. Overall, there seems to be an implicit or explicit agreement among specialists that consider the motifs are graphic and conceptual units of visual speech, though many disagree about their formal and semantic definition.

Definition

Motif is an expressive and consistent component of design, characterized by their shape, color, size, position, orientation, texture, etc. (Fiore 2009). Motifs integrate bigger compositions while they articulate spatially and meaningfully with other elements. It is then an expression unit and, as such, expresses a particular view of the world; thus, it is valid to be used as a unit of analysis (Aschero 1988).

According to Gradin (1978), who has been particularly interested in the notion of motif, it is a representation that was made in the same time (execution unit) and with a certain sense (motivational drive unit).

Key Issues and Current Debates

The classification of motifs is another challenge faced in archaeological art studies. Many authors propose a distinction between *simple and complex motifs*. The first are those formed by a single element; all its lines, or its entire surface, are connected into a single entity, displaying a continuous trace which is the result of a unitary creative act. Complex motifs are likely to be constituted by two or more elements that are linked together based on morphological grounds or content (Gradin 1978). This division is based on the number of items that a motif integrates and is common in rock art studies and also in studies of the decoration of artifacts, especially ceramics (Rice 1987).

To some extent, the concept of motif is independent of the technical support and execution,

beyond the conditioning that these factors impose. Thus, classification criteria refer primarily to issues of composition, morphology, analogy, and association. In this regard, it is appropriate to consider another parallel way of grouping the motifs – agreed by most researchers – depending on the presence or absence of a recognizable formal correlate with the physical world. The division between figurative and nonfigurative patterns derives from this.

The *figurative motifs* answer to an attempt to apprehend the external forms. In that sense, in this category all the images which allow – partially or totally – to recognize objective world elements of both realistic (recreation or model representation of physical existence) or fantastic (creation or presentation of imaginary figures which combine or reformulate real elements) are included (Gordillo 2009). In contrast, in the *nonfigurative motifs*, no direct empirical analogies are recognized and are presented as linear elements, geometric shapes, irregular shapes, spots, stains, etc.

Indeed, the precise boundaries between figuration and nonfiguration are often arbitrary, and it is difficult to establish whether there is a difference of essence or grade between the two categories – a problem also found with Western art, which is where this classification comes from. It is likely that many nonfigurative motifs have an origin or figurative counterpart; it is appropriate to consider the *geometric reduction* process, a phenomenon that leads explicit figures of varied figurative levels to the reduction in abstract figures (Leroi-Gourham 1989). Also, in the social context of their production, nonfigurative motifs could represent or be associated with real but unknown referents because of the semantic and temporal distance that separates emic viewers from etic categories (Groupe 1993).

Ethnographic research done by Dolmatoff Reichel (1985) illustrates this point. This study focused on certain geometric or "abstract" motifs which were recurring throughout the material culture of the northwest Amazon Tukano Indians. These motifs, according to the author, are inspired by phosphenic hallucinatory images and also form a coded system where each of those have a fixed ideographic sign value, aspects that are likely to be overlooked by us in the study of past societies.

In short, these observations lead us to a critical problem in the archaeology of art. Motif, as part of a system of symbols, is a reference to something else. And what is communicated by the symbol depends on the viewer's cultural background. If this motif shares the same visual system as the one of the producer, what is expressed on the motif and what is communicated to him can be very similar. For archaeology, where prehistoric art manifestations are studied, this merging is not possible; however, beyond the original semantic and elusive content, shape analysis provides a means to access the way in which the art system operates (Ross et al. 2008).

From the perspective of structural analysis, the proposal is to go beyond the factual or descriptive level and, without the imperative to interpret the allegorical dimensions or the conventional meanings associated originally with each motif, hold the possibility of accessing the unconscious deep and essential meanings immanent to the thought systems of society (see Criado Boado and Penedo 1993). Using a formal analysis of oppositions, the motif of representation that applies to the artist's intention reveals their articulation in the designs and the principles that structure them. In this line of analysis, Kusch (1991) considers that the motif presents "attributes of composition" (view, orientation, attitude, distribution, etc.) pointing to structural and conceptual aspects, where deep meanings live and operate replacing their immediate morphology.

Mound Building, Social Complexity and Horticulture in the Lower Paraná River

Mariano Bonomo[1] and Gustavo G. Politis[2]
[1]CONICET-División Arqueología, Facultad de Ciencias Naturales y Museo, Universidad Nacional de La Plata, La Plata, Argentina
[2]CONICET, INCUAPA, Facultad de Ciencias Sociales, Universidad Nacional del Centro de la Provincia de Buenos Aires, Olavarría, Argentina

Introduction

Pre-Hispanic earth mounds, known as "cerritos," "cerros," "túmulos," "lomas," "islas," "bordos" and "montones" (in Spanish), "aterros" and "tesos" (in Portuguese), and "îvî choví" (in Guaraní), across southeastern South America are one of the most conspicuous cultural manifestations preserved in the vast lowlands. In most cases, these mounds are located in flood zones. They have been interpreted as a specific adaptive strategy used by different South American indigenous populations, from the middle Holocene, to occupy fluvial plains that are periodically flooded and have high biodiversity. The use of land to build structures with dry surfaces for settlement and other functions allowed them to access the rich aquatic and terrestrial resources available within these environments surrounded by rivers, lagoons, and wetlands. Many of these mounds are in the huge La Plata River basin (Fig. 1), in its main tributaries such as the Upper Paraguay River, the Lower and Middle Paraná River, the Lower Uruguay River, in eastern and northeastern Uruguay, southeastern Brazil, and possibly in Esteros del Iberá, although the Iberá area has not been systematically studied. Hundreds of elevations were recorded in the floodplain between the Dulce and Salado rivers of Santiago del Estero. Some of them are natural levees whose upper parts were unintentionally elevated by people (Martínez et al. 2011), and some others would be artificially built mounds with depressions possibly linked to sediment extraction (Togo 2004).

Mound Building, Social Complexity and Horticulture in the Lower Paraná River, Fig. 1 Main areas with earth mounds studied in the La Plata basin and neighboring regions, based on research and surveys by Anderson Marques García, Rafael Milheira, Irina Capdepont, Camila Gianotti, José Iriarte, Rafael Corteletti, Francisco Noelli, Jonas Gregorio de Souza, José Togo, Constanza Taboada, Gabriela Ortiz, Carlos Pusineri Scala, Pedro Ignácio Schmitz, Jose Luis dos Santos Peixoto, Jorge Eremites de Oliveira, William Denevan, Clark Erickson, Heiko Prümers, and Carla Jaimes Betancourt. Note: In the zones of greater concentration, the symbol represents archaeological localities with several earth mounds. With the exception of Garcia (2012), there are no synthesis maps on their spatial distribution, and many areas have not been surveyed, so this represents only a minimal number of mounds

Within the La Plata basin, small earth mound structures were also recorded in a few sites of the so-called San Francisco Culture in Jujuy province (Ortiz 2003).

In some areas of the lowlands in the La Plata basin, the concentration of earth mounds is high and has been well studied. In the Gran Pantanal of the Upper Paraguay River (Pusineri Scala 1973; Eremites 1996; Peixoto 2005), in the Yaguarí and Caraguatá basins in Uruguay (Gianotti 2016), and in the Laguna Merim (Bracco et al. 2000; see review in Iriarte et al. 2016), more than 1000 mounds were recorded in each region. Thousands of mounds exist in the Brazilian highlands, linked to the subterranean and enclosure complexes of the Taquara/Itararé Tradition, although these mounds are not associated with flood zones. Although not in the La Plata basin, the Llanos de Mojos shows

several thousand artificial mounds related to other important engineering works such as raised fields for cultivation, rectilinear causeways or raised roads, and canals for water distribution and navigation (Erickson 2000; Prümers and Jaimes 2014). Despite some common characteristics (most are in flood zones and were built in the late Holocene), the earth mounds have specific regional traits and belong to different cultural contexts.

In the Lower Paraná and Lower Uruguay floodplains, the earth mounds are the most visible features of the archaeological record and were early recognized as constructed structures in the first archaeological investigations of the region in the late nineteenth and early twentieth centuries. Like with the tesos of Marajó Island, the lomas of Llanos de Mojos, and the sambaquí shellmiddens in south-central coast of Brazil, since the recognition of the earth mounds of southern Mesopotamia (region bounded by the Paraná, Uruguay, Iguazú, San Antonio, and Pepirí Guazú rivers), it has been debated whether their genesis was cultural, natural, or a combination of both. Current studies have confirmed that the indigenous populations of the Lower Paraná (Bonomo et al. 2011a; Politis et al. 2011; Castiñeira et al. 2013, 2014) and Lower Uruguay (Castro 2016) not only occupied natural high places but also had the ability to modify and transform the landscape by building mounds. These studies have confirmed that a great number of the settlements were mounds formed partially or totally by anthropic action, resulting from both accretion due to repeated human occupations and intentional elevation of the ground by addition of clays with plastic properties and other thicker cohesive materials like potsherds. Identifying which of these two processes occurred in each case requires detailed geoarchaeological analysis, which are very scarce in the study area. In addition, in most cases, the anthropic elevation of the habitable surface took advantage of pre-existing natural elevations, such as levees and dunes.

Recent regional research in the Upper Paraná Delta has associated some of the mounds of the Lower Paraná River with societies characterized by some degree of complexity or by social hierarchies evidenced in at least first-order community leadership and with small-scale horticultural practices assigned to the Goya-Malabrigo archaeological entity (Fig. 2, Politis and Bonomo 2012).

Mound Building, Social Complexity and Horticulture in the Lower Paraná River, Fig. 2 Main features of the material culture associated with Goya-Malabrigo archaeological entity

Both aspects have already been suggested through certain ethnohistorical information and archaeological remains (Serrano 1930; Ceruti 2003). However, only recent evidence generated by current methods (e.g., studies of starches and phytoliths) has made it possible to approach these issues in the light of contemporary theoretical approaches, shifting the axis of the discussion of the earth mounds of the Lower Paraná and Lower Uruguay rivers. At present, the study of the mounds can neither ignore the processes of social complexity nor lack an integral evaluation of the economy of the societies that built them.

This contribution summarizes the main issues related to the indigenous populations that occupied the alluvial plain of the Lower Paraná River during the late Holocene, especially since ca. 2000 years BP. This extremely flat alluvial environment was inhabited by populations that constructed earth mounds, had a diet based on wild resources complemented with house-garden horticulture, and revealed a certain level of social complexity, characterized as rank societies. This region had intense cultural dynamics that included the local groups as well as the Guaraní and possibly the Arawak, both descendants of populations probably originating in the Amazon basin but certainly expanding beyond it. The diversity of ethnonyms that the first European conquerors used to describe the Lower Paraná groups in the early sixteenth century (Chaná-Timbú, Timbú, Mbeguá, Mocoretás, Carcaraes, Corondás, Colastinés, Guaraní, among others) reflects this dynamics and is the result of evolutionary/adaptive processes and of particular historical trajectories.

Environment

The Paraná River stretches about 4200 km along the La Plata basin, the second largest hydrographical basin in South America, after the Amazon River. Along the Paraná, the most important river in the basin, a narrow gallery forest acts as a biological corridor in a north-south direction for thousands of kilometers, connecting the tropical forests of Brazil with the temperate grasslands of the Argentine pampas. The course of the Parana River has been divided according to several criteria. In this chapter, we use the most usual division in Argentina, where the river travels around 1930 km: the Upper Paraná, from its source to the confluence with the Paraguay River; the Middle Paraná from there to the beginning of the pre-Delta in the city of Diamante; and the Lower Paraná, comprising mainly a large delta, about 300 km long by 60 km wide (maximum), until it flows into La Plata River. The Delta, classically divided into Upper, Middle, and Lower Delta (Fig. 3), is a wide alluvial floodplain (around 14,000 km^2) consisting of a set of islands surrounded by narrow waterways and formed by the regular accumulation of sands, clays, and limes deposited mainly by the river.

The Delta, like the alluvial plain of the Middle Paraná, is a very dynamic environment, with a complex hydrological regime that subjects the low zones to periodic floods at different times of the year. These periodic changes in the river level blurred the boundaries between the islands and the aquatic environment. Heavy precipitation, especially in the tropical and subtropical zones of Brazil, frequently associated with the El Niño weather phenomenon, also causes extraordinary floods that partially or almost totally cover the deltaic environment. The Paraná River is the largest freshwater fishing area in Argentina since it harbors a great variety of aquatic resources that are continuously renewed with the movement of the waters. During the floods, nutrients are added to the soils with the agricultural potential of the levees, but there are also important changes in the distribution of the biota and therefore of the main usable resources. On the one hand, the space for animals, such as marsh deer (*Blastocerus dichotomus*), capybara (*Hydrochaeris hydrochaeris*), and coypu (*Myocastor coypus*), is limited and concentrated on high places, which facilitates their hunting. On the other, fish and mollusks are dispersed making it difficult to obtain them, although when water recedes, the fish that are trapped in secondary courses and in shallow water bodies can be harpooned.

The coastal plain, together with the subaerial platform constituting the Paraná Delta sensu *lato*,

extends over a gently sloping terrain genetically linked to the transgressive-regressive Pleistocene-Holocene events (Cavallotto et al. 2005; Codignotto 2004). According to the paleoenvironmental reconstructions, the pre-deltaic tidal plain would have been formed after the end of the transgression, which reached its highest level ca. 6000 BP. Later on, during the first regressive stage, the coastal plain began to take shape from the accumulations of different sedimentary facies: deltas, plains with beach ridges, beaches, and tidal and coastal lagoon plains. However, it was during the second stage of the regressive event, subsequent to 4000 BP, that the coastal plain acquired its present configuration. Therefore, the human occupation of the area could have developed on the mud of the pre-deltaic tidal plain or, at a later time, on alluvial clayed mud or mud sediments deposited by floods in the lower Paraná River (Castiñeira et al. 2013).

Historical Background

Archaeological investigations on the Lower Paraná began at the end of the nineteenth century and were pioneering in Argentina. The earliest references to archaeological materials in the region – corrugated urns with lid and polychrome vessels, both from the Guaraní – dated ca. 1818 and 1858 and were made by Francisco Javier Muñiz in a report on the islands of the Paraná River presented to the government and by Marcos Sastre in his famous book *El Tempe Argentino,* respectively. In 1877 Estanislao Zeballos and Pedro Pico excavated the site called Túmulo de Campana in the Buenos Aires province, one of the first archaeological excavations in Argentina. While this site was erroneously attributed to the Guaraní, it was the first identification of an anthropogenic earth mound that had been used for both settlement and funerary purposes. According to the excavators, it was an artificial mound, where they recovered human skeletons, remains of domestic activities, bone tools, and pottery with zoomorphic appendages of birds, mammals, and mollusks.

Contemporaneously in 1877, Ramón Lista described two burial mounds in the south of Entre Ríos province and attributed to them a purely anthropic origin. Later in 1880, Florentino Ameghino correlated these mounds and Túmulo de Campana with the burial mounds of southern Brazil and of Uruguay, proposing the hypothetical existence of a "people of the tumulus." At the end of the nineteenth century, the investigations of Juan Bautista Ambrosetti in the Goya archaeological sites on the Paraná River, Corrientes province, showed the great areal dispersion of the ceramic style characterized by zoomorphic appendages. This author associated these materials with those of Túmulo de Campana, which constituted the first attempt at regional integration. Later, based on the documentation and a sketch, Luis Maria Torres considered that one of the excavated sites was an artificial mound and named it Túmulo del Usuró.

In the early twentieth century, Luís María Torres directed research in the Paraná Delta from the La Plata Museum, thus initiating a long institutional tradition of archaeological studies in the area. He carried out intense field work on isolated mounds in flood zones and, in agreement with Lista, considered that they had been raised by the indigenous people to avoid flooding (Fig. 4). He argued that although the sandy nuclei of the mounds, which he called túmulos, were natural, their height had been increased by humans, who had added layers of humus and clay and cultural remains (Torres 1911). Torres attributed the differences observed in the decoration of the pottery of the Delta to different ethnic groups of historical times, although in the sector that he studied, the zoomorphic appendages were very scarce. One of his contributions was the detailed description and analysis of the abundant human skeletons found in the Delta.

Torres's proposal was later refined by Félix Outes, who distinguished three successive groups based on pottery and other elements. According to Outes (1918), the first group had a very simple and "primitive" pottery with few incised or painted items associated with bone tools and burials on elevated grounds, "apparently

Mound Building, Social Complexity and Horticulture in the Lower Paraná River, Fig. 4 Sketch of Túmulo I del Río Carabelas, excavated by Luis María Torres

tumulus." The second group were builders of mounds, used for burials, who decorated pottery depicting humans and more frequently animals (which, according to Torres, could be evidence of Arawak influence), few stone instruments, and bone tools. The third group, of Guaraní origin, was characterized by large funerary polychrome or corrugated urns, polished axes, and scarce bone tools. Such cultural patterns were later widely accepted by the different researchers who studied the archaeology of the Paraná River.

In 1923, Joaquín Frenguelli and Francisco de Aparicio excavated some elevations outside the Delta, in the vicinity of Malabrigo River, on the right bank of the Paraná alluvial plain in Santa Fe Province. They stated that these elevations would not be burial mounds but old consolidated dunes on which indigenous people settled to protect themselves from floods. According to Frenguelli and de Aparicio (1923), the elevations represented remains of a dune chain, which ran parallel to the Malabrigo course and was cut transversely and shaped like ridges by the action of the water that flowed down to the river bank. Over time the high sectors were fixed by vegetation and occupied by indigenous populations. Due to Frenguelli's considerable stratigraphic experience as a geologist, his work has highly influenced later studies on mounds even to date. It led to interpretations that indigenous occupations had occurred only on natural elevations. This concept was extended to the archaeological record of a vast region, including the Argentine Northeast and the so-called Mesopotamia Santiagueña (between the Dulce and Salado rivers).

In the same year, 1923, Pablo Gaggero and Octavio Fernández of the La Plata Museum excavated a small round mound in the Lower Delta (Fig. 5) and suggested that it was of cultural origin. In 1925 the American archaeologist Samuel Lothrop excavated three archaeological sites in the Lower Delta and its immediate plain and, according to the ethnohistorical accounts, attributed one to a Guaraní village (Arroyo Malo site), another to a settlement of the Querandíes (Arroyo Sarandí site), and the third one to the Chaná-mbeguá or Chaná (El Cerrillo site). The author held that the last two records formed a single cultural unit, thus homogenizing the diversity identified in the archaeological record by other researchers. As for the earth mounds, Lothrop (1932: 186) found no evidence to consider the elevation excavated at El Cerrillo as partly artificial and argued that "the general distribution of rubbish indicated that the living surface had been gradually elevated as a result of occupancy." In 1939 Alberto Rex González investigated the Cerro Grande del Paraná Pavón archaeological site, which he differentiated from the elevations of eolic origin identified by Frenguelli and from the mounds with intentional addition of sediments studied by Torres. In agreement with Lothrop, he argued that the site was a small natural elevation that gradually increased in volume by natural deposit and in smaller proportion by anthropic action.

Mound Building, Social Complexity and Horticulture in the Lower Paraná River, Fig. 5 Two general views of Túmulo II del Brazo Largo, excavated by Gaggero and Fernández

In 1926, Héctor Greslebin conducted controlled stratigraphic excavations in several mounds in the floodplain of the Lower Uruguay River and stated that the mounds were totally or partially constructed (e.g., Túmulo de Lucuix and Sambaquí of Puerto Landa, respectively) although in agreement with Torres, he supported the coexistence of occupations on elevations of eolic and fluvial origin. For Greslebín (1931), the mounds were created or conditioned for protection from the floods of the Uruguay River. Other important research on Uruguay River was that of Pedro Krapovickas, who re-excavated some of the mounds studied by Greslebin. Krapovickas presented a detailed stratigraphic profile of Cerro Godoy (or Sambaquí of Puerto Landa) and Cerro de Los Pampas (or Túmulos de Estoponda) and concluded that the former was accretional, a dump raised by accumulation of waste, while the latter was a mound built on a pre-existing dune, by "consciously or unconsciously mixing" archaeological materials.

Based on his long term investigations, Antonio Serrano established the "fundamental lines" of the pre-Hispanic past of the Paraná and Uruguay rivers, which were valid until the 1970s. In a way, Serrano introduced some concepts of the North American culture history approach. He elaborated an explanatory model on the historical development of the Argentine Northeast or

Mesopotamian littoral, based on the spatial variations of the archaeological ceramics and the location of the different ethnic groups that the European chroniclers recognized in the sixteenth and seventeenth centuries. He proposed an initial ceramic occupation of populations from "Cultura Entrerriana" (Entre Ríos Culture) that would later receive, in the Paraná and Lower Uruguay, the contributions of more advanced ceramist groups of Amazonian origin, which he called "Ribereños Plásticos" (Riverside craftspeople). He stated that although the basic characteristics of the previous pottery were maintained, with these contributions, artistic representations of animals were incorporated in the ceramics (zoomorphic appendages, especially depicting birds and mammals). This author considered that the changes in the pottery reflected the spread of innovative ideas and the dispersion of new populations that arrived in the region by migratory waves from neighboring areas. Like de Aparicio, Badano, and Gaspary, among others, Serrano argued that the archaeological materials of the "Ribereños Plásticos" belonged to the Chaná-Timbú aborigines of the time of the conquest. In his general classification of the indigenous populations of the entire Argentine territory (Serrano 1941), he classified the Paraná populations as "intermediate agriculturalists" who were organized in "grandes cacicazgos" (great chiefdoms). Serrano associated long cylindrical artifacts, called "pylons," made with allochthonous lithic raw materials, with symbols of political or religious authority (Serrano 1930). He summarized the discussion about the existence of cerritos or mounds, and although he knew about the existence of mounds built in the Delta, following Frenguelli, he thought that in most cases (mainly in the Middle Paraná), the mounds were remains of ancient consolidated dunes or levees with no significant modifications, on which the indigenous populations settled (Serrano 1950).

In addition, from a more eclectic culture history perspective, Ciro René Lafon conducted research in several sectors of the Lower and Middle Paraná and the Lower Uruguay rivers. He was rather skeptical about the cultural origin of the Delta cerritos and preferred to call them elevations, instead of mounds or tumulus, for the sake of objectivity, although he recognized the anthropic over-elevation by accretion. For example, he argued that El Aserradero site was placed on a levee whose height was increased by the remains and waste left by the inhabitants. Concerning the mounds of the Middle Paraná, he wondered whether they were true "tumulus or tells" or accumulations of dwellings and trash where the dead were buried. An interesting observation by Lafon (1971: 131), based on Palavecino, was that he attributed some type of horticulture ("primitive paleoamazonian agriculturalists") to what was later called Goya-Malabrigo. This somehow anticipated the later confirmation of the existence of horticulture in these populations.

After her participation in the group led by Eduardo Cigliano, Maria Amanda Caggiano focused on the Lower Delta of Paraná and Lower Uruguay. By analyzing the ceramic pastes and tempers with which the ceramic vessels were manufactured and their decoration styles, she expanded the archaeological categories of Serrano (e.g., that of the Ribereños Plásticos and the Ibicueña). Following this author's outline and based on excavations of new sites located on levees; paleo-levees or marshland borders, among them Isla Lechiguanas I; and several ^{14}C datings, Caggiano (1984) aimed to establish a chronological sequence that would integrate the regional variability of the archaeological materials.

In the mid-1980s, based on his work in the Middle Paraná, Carlos Ceruti proposed a sequence of "two cultural types": Cancha de Luisa and Goya-Malabrigo. An important antecedent was the article by Schmitz et al. (1972), based on materials excavated in 1948 by González in the vicinity of Goya. Later, Ceruti (2003) proposed a model of cultural development that integrated the cultural entities proposed within an ecological framework. We will focus here on Goya-Malabrigo (=Ribereños Plásticos), because it is better characterized and because abundant earth mounds have been detected. It derives its name from the union of two of the most widely studied localities at the beginnings of archaeology in the Argentine Northeast: Goya, where

zoomorphic appendages were first presented in detail, and Malabrigo, about 55 km southwest of the first archaeological sites. Both localities were early recognized as the centers of an area with the greatest abundance of plastic representations, whose distribution reached the Lower Delta of the Paraná, though with lower density (Serrano 1950; de Aparicio 1949). Ceruti did not discuss the earth mounds in depth, but based on observations from current settlers who continue to erect mounds to resist flooding, he suggested that housing areas could have been elevated by both accretion and intentional sediment transport.

Since the mid-1990s, Alejandro Acosta and Daniel Loponte carried out research in a restricted area of the Lower Paraná floodplain (the bajíos ribereños), continuing the study of sites reported by Lafon and adding some new ones. However, they did not identify the presence of earth mounds. They even argued that the cerritos of Entre Rios were actually natural levees that were occupied and that classical sites in the literature, such as Túmulo de Campana, would be located on natural geoforms. Recently, they reported on occupations on dune formations and recognized a few anthropic mounds in the flood plains of southern Entre Ríos.

Since the 1990s, a series of studies on mounds has been carried out in the Upper Delta and on the right bank of the Middle Paraná (Santa Fe), by Universidad Nacional de Rosario. A noteworthy investigation is the excavation of earth mounds at Cerro El Castaño 1 and 2 by Juan Nóbile and Silvia Cornero in the former area (Cornero 2009). In the latter, Cornero excavated La Lechuza site, and Campos (2001) made sedimentary and distribution studies of the archaeological materials and concluded that it is an elevated structure with anthropic contribution. As for Cerro Aguará, Laura Pérez Jimeno (2007: 75) mentions that it is one of the highest cerritos in the area but believes that its genesis is due to the formation of the levees. However, she does not rule out anthropic activity in the contribution of the materials.

Since 2006, our research team has conducted archaeological investigations of the Upper Delta of the Paraná and its adjacent plain. As a result of our field work, 84 archaeological sites were surveyed, 25 of which are on the plain and 59 on the islands. We found that 37 of these island sites are earth mounds. We also conducted research in the classical archaeological sites of the Paraná, such as Cerro Grande at Isla de los Marinos and Cerro de las Pajas Blancas 1, and studied old museum collections of sites characterized by their excavators as mounds, namely, Túmulo de Campana, Túmulos I and II del Paraná Guazú, Túmulos I and II del Brazo Largo, and Túmulo I del Brazo Gutiérrez, among others. To evaluate the archaeological potential of the Upper Delta, test pits were performed in more than 30 sites, and larger excavations were carried out in seven of them: Cerro Tapera Vázquez, Los Tres Cerros 1 and 2, Laguna de los Gansos 1 and 2, Cerro Farall, and Laguna del Negro (Bonomo et al. 2011b, 2016; Politis et al. 2011; Apolinaire 2017). In addition, this project included detailed geoarchaeological studies of the cerritos, thus facilitating the discussion of their genesis and formation with a novel dataset (Castiñeira et al. 2013, 2014). More recently GIS tools and concepts derived from graph theory have been combined to analyze the Upper Delta archaeological data (basically mounds), as done by Apolinaire and Bastourre (2016). These authors found that there is a positive correlation between mound size and centrality values (both in the hydrographical network and in the sites network) and that the most prominent places are central in terms of the cultural landscape. They also proposed that the position within interaction networks conditioned the existence of hierarchical relationships and the chances to accumulate foreign goods. In addition, complementary bioanthropological studies were done to better understand the funerary practices conducted in these mounds (Scabuzzo et al. 2015).

Linked to our project, Juan Carlos Castro has investigated the Lower Uruguay River from the Argentine side since 2009 and has registered several mounds and studied museum collections of others. In particular, he conducted a detailed excavation of Cerro de Boari 3 archaeological site, near the mouth of the Gualeguaychú River, and refined the chronology of its formation. These studies (Castro 2016) add to the classics of Greslebín, Krapovickas, and others on the

Uruguayan bank, such as Túmulo de La Concordia and Cerrito de La Blanqueada, and have made it possible to conduct modern geoarchaeological studies on the genesis of the cerritos on Uruguay river.

Key Issues/Current Debates

The natural or artificial origin of the pre-Hispanic mounds of the Lower Paraná and Uruguay rivers has been subject of active debate. As explained in the previous section, different alternatives have been proposed to explain the genesis of the mounds: massive events of anthropic construction, growth by accretion derived from successive human occupations, use of dunes or levees, and combination of natural elevations at the base and anthropic accumulations at the top. At present, most authors recognize human participation (intentional or not) in the elevation of the mounds (Campos 2001; Ceruti 2003; Cornero et al. 2007; Nóbile 2002; Bonomo et al. 2011a). What seems clear today is that not all mounds have the same origin and development as they correspond to different cultural and natural processes.

According to the ^{14}C ages obtained (Fig. 6), stable human occupation of the Upper Delta

Mound Building, Social Complexity and Horticulture in the Lower Paraná River, Fig. 6 Chronology of human occupations on mounds in the Upper Delta of the Paraná River in the context of the main cultural events at local

would have taken place from ca. 2000 years ^{14}C AP, rather long after the area was available, after the last Holocene transgressive event. At least it is from that date that the first evidence was obtained for the construction of earth mounds at Los Dos Cerros 1 archaeological site (Castiñeira et al. 2017). These constructions provided stable settlement surfaces, which were little affected by floods. The earth mounds were erected to establish residential areas – in some cases forming small villages – where domestic activities and funeral practices were carried out. These practices, which included primary and secondary burials and assemblages of skeletal parts, surely turned the spaces devoted to the ancestors into places where the collective memory was constructed and reaffirmed. It has also been suggested that some sectors of the mounds could have been used as gardens, probably in the domestic context (Sánchez et al. 2013). These structures may form groups of two or three, but they are usually separated from each other, showing a predominantly dispersed settlement pattern. This does not mean that they were isolated and disconnected units; on the contrary, they appear to have been integrated into local systems of intragroup interaction and supraregional exchange networks (Apolinaire and Bastourre 2016) that ensured the arrival of personal adornments made of metal and other exotic products.

As expressed for some time (e.g., Outes 1918; Gaspary 1950; Serrano 1950; Caggiano 1984; Bonomo et al. 2011a), the genesis of the Lower Paraná-Uruguay cerritos is not uniform and neither can they be assigned to a single archaeological entity. Although many earth mounds have been attributed to Goya-Malabrigo in the Lower Paraná and Lower Uruguay rivers, other earth mounds have been detected in sites not attributable to Goya-Malabrigo (e.g., Túmulo II del Brazo Largo, Túmulo I and II del Paraná Guazú on the Lower Paraná Delta), some of which have been assigned to Ibicuí or Ibicueña facie (Serrano 1950; Caggiano 1984).

Concerning the genesis of the elevations, at least three basic types have been described:

(a) Earth mounds that were totally or partially constructed with the intentional contribution of sediments (clay and thicker materials), usually resulting from multiple occupations over several centuries.
(b) Accretional earth mounds, deriving from human occupation (without intentional contribution of sediments) on naturally elevated landscape geoforms. The height is increased by the accumulation of materials discarded and abandoned in the settlements (e.g., housing collapse).
(c) Elevations that are not earth mounds but natural geoforms where human occupation did not alter the height. In the Lower Paraná and Uruguay rivers, the most widely used geoforms in types b and c are levees and dunes.

One of the main difficulties in studying the genesis of the Lower Paraná earth mounds has been the shortage of systematic and intensive studies. In recent years, high resolution planimetric surveys with total station (Fig. 7) and geoarchaeological studies in some sites of the Upper Delta have shown the three types of elevations (Bonomo et al. 2011a; Politis et al. 2011; Castiñeira et al. 2013, 2014): Los Tres Cerros 1, a good example of an anthropic construction; Cerro Tapera Vázquez, representing the second group (an occupation on a naturally elevated form with anthropic accretion); and Laguna de los Gansos 1 and 2, exemplifying occupations on levee without altering height. In the following section, we summarize the information of these sites, because in addition to the detailed geoarchaeological studies, the contextual archaeological data and the relatively adjusted chronology allowed us to address the other two issues related to mounds: social complexity and economy.

Los Tres Cerros 1 (LTC1)

Archaeological locality Los Tres Cerros (Victoria, Entre Ríos) is located on the left bank of the Zanjón Almada and composed of three earth mounds in close proximity, surrounded by extensive marshland after flooding. These elevated sites are generally protected from flooding and thus

Mound Building, Social Complexity and Horticulture in the Lower Paraná River, Fig. 7 Planimetric surveys of mounds with total station, jointly conducted with Camila Gianotti: (**a**) Cerro Puesto Acosta, (**b**) Cerro El Durazno 1, (**c**) Cerro El Lucerito, (**d**) Cerro Tejeira, (**e**) Cerro Barrancas; (**f**) digital elevation models of Cerro Grande de la Isla de los Marinos and (**g**) Cerro Lote 11. Note the depressed zones surrounding some of the mounds that could have functioned as sediment extraction areas for the construction

function as shelter for tree species in a grassland-dominated space. The archaeological materials are distributed in the three mounds, in the adjacent plain, and in three microreliefs near the cerritos. Successive campaigns between 2008 and 2012 carried out tens of stratigraphic test pits, planimetric surveys of the mounds and of their constructive layers, and excavations, with 33 m^2 excavated at the top and base of Los Tres Cerros 1 and 4 m^2 at the top of Los Tres Cerros 2. These efforts made it possible to conduct archaeological, geological, and botanical studies in this locality.

Mound Building, Social Complexity and Horticulture in the Lower Paraná River, Fig. 8 General view of Los Tres Cerros 1 mound

LTC1 (Fig. 8) is the central mound relative to the other two elevations, standing out from the surrounding flat terrain as the highest structure. It is an artificial construction that was raised more than two meters above the plain with the ad hoc addition of significant amounts of sediments and, to a lesser extent, discarded and abandoned remains during occupations. Castiñeira et al. (2013) reported that the mound structure presents anthropic accumulations of sediments, in situ burnt soil, and archaeological materials. The mound is composed of different levels of accretion with a high content of organic matter that contrasts with the poor soils of the area. Significant textual and mineralogical discrepancies were found between the natural sediments of the adjacent plain and those of the mound, modified by fire and the addition of sherds, charcoal, valves, and bones. These thicker textured materials would have been intentionally included not only to increase the height and widen the base of the mound but also to strengthen the fine sediments and maintain the integrity of the structure. The fire was also used to consolidate and protect the structure from erosive agents, eliminate weeds, condition the ground, and harden possible dwelling floors. The compositional differences between argilominerals of the mound structure and the adjacent natural horizons indicate that the sediment extraction area used for the mound elevation was not related to the alluvial sediments of the surrounding plain. On the contrary, the selection of mud with cohesive properties from specific areas was favored because it met construction requirements (Castiñeira et al. 2013).

Building this mound required moving more than 1700 m^3 of sediment in different stages of community work distributed over centuries. The 21 radiocarbon dates obtained in LTC1 show that the site was occupied between 1200 and 560 years BP, with prolonged periods of stability alternated with episodes of abandonment and later reoccupation. Throughout this period, populations devoted to hunting, gathering, fishing, and horticulture used the mound for domestic activities and funerary practices (Politis et al. 2011; Scabuzzo et al. 2015). At the top of the mound, these domestic activities were identified through the presence of bonfires, wells with abundant fish remains, possible postholes (circles

5–11 cm in diameter preserved in the burnt soil), and the aforementioned dwelling floors. The waste at the top was cleaned, as shown by the dump detected at the base of the mound, containing high density of sherds, fractured and burned animal bones with cut marks (Bastourre 2014). This concentration of materials at the base of the mound also received contributions of materials removed and redeposited by natural agents.

The chronology, geographical location, and stylistic and technological characteristics of the ceramics are associated with the Goya-Malabrigo archaeological entity (Ceruti 2003; Politis and Bonomo 2012). The pottery dominates the artefactual set of the site with more than 30,000 potsherds found in excavation (Di Prado 2015). Manufacturing was carried out on site, as indicated by the presence of clay dough and rollers and ceramic flatteners. The characteristic "campanas" (=bells) made of pottery were found in LTC1. These campanas are cylinder-shaped or truncated cone pieces, open at the bottom, usually with a zoomorphic appendage at the top. Other pieces were found, such as a vessel with three inner compartments, a spindle whorl, trimmed silhouettes in the shape of psittacines (including macaws and parrots), and solid three-dimensional appendages depicting birds, mammals, reptiles, and mollusks. Noteworthy appendages include heads of bird that have colorful and bright plumage (psittacines), birds of prey (falconiforms), and solitary animals that are dangerous to humans (e.g., ophidians). Drag-and-jab was the predominant decorative technique, used for drawing straight and stepped lines, zigzags, and geometric figures. Lithic artifacts are very scarce, and the raw materials came from different geological formations located over 50 and 230 km from LTC1. Different types of bone artifacts have also been recovered: grooved, semi-grooved and flat tips with and without peduncle, harpoon tips, and a pendant.

Abundant bones and teeth were found, corresponding to coypu (*Myocastor coypus*) and capybara (*Hidrochoerus hidrochaeris*), the most widely represented species of rodents, which presented fractures and traces from disarticulation of the carcasses, leather extraction, and meat consumption (Bastourre 2014). Other resources are the wild cavy (*Cavia aperea*), carnivores such as neotropical otter (*Lontra longicaudis*), pampean fox (*Lycalopex gymnocercus*), freshwater clams (*Diplodon* sp.), and very low frequency of ampullarids. In addition, fish skull bone, thorns, and vertebrae were found: tararira (*Hoplias malabaricus*), sábalo (*Prochilodus platensis*), boga (*Leporinus obtusidens*), chanchita (*Cichlasoma facetum*), and common armado (*Pterodoras granulosus*). In general, this faunistic composition, which indicates an economy strongly oriented toward aquatic resources, is frequent in the vast majority of sites in the Lower and Middle Paraná River (Ceruti 2003; Pérez Jimeno 2007).

Archaeobotanical studies (Sánchez et al. 2013) in LTC1 identified phytoliths of palmaceous plants, *Equisetum* sp., *Canna* sp. (achira tuber), and Orizeae (family that includes wild rice). Further evidence of manipulation of wild vegetables was also found in morphotypes related to *Zea mays* (maize) and Cucurbitaceae. The flotation technique permitted the discovery of carbonized maize seeds in levels dated between ca. 580 and 860 years BP (Colobig et al. 2015). Maize phytoliths were also detected in sedimentary samples from the lower levels of the site dated before 1030 years BP. These results support the presence of a horticultural component in the subsistence of LTC1 inhabitants, from the beginning of the mound elevation. However, according to recent isotopic studies, the contribution of cultivated plants such as corn would have been complementary.

Another finding in this domestic context was that of human bone remains of at least 16 adult, adolescent, and infant individuals of both sexes (Scabuzzo et al. 2015). These human bones were arranged in two sectors of the site: at the base of the mound, where most of the individuals were found, and at the top, where red painted remains of a single individual were recovered inside a hearth. At the base of the mound, the layers containing the skeletons presented abundant ceramic and food remains, among them mandibles and teeth of coypu and burned vertebrae of fish, as well as valves of *Diplodon* sp. arranged in layers above and below the human burials. Although

some elements, such as valves or large fragments of in situ broken vessels, are clearly associated with burials, other materials were surely part of the sediments where the skeletons were buried and with which they were covered. In fact, below the highest concentration of human skeletons, the previously mentioned dump was recorded.

At LTC1, a differential manipulation of the skeletal remains is reflected in elaborate mortuary practices (Scabuzzo et al. 2015). These practices included primary burials, secondary packages, and the arrangement of isolated anatomical parts with soft tissues that kept them articulated. The bodies were therefore subject to various treatments and different trajectories of burial, exhumation, and reburial. The seven ^{14}C dates of these human remains comprise between 650 and 850 years BP, subsequent to the beginning of the construction of the mound around 1000 BP. The available information indicates that the mound was first a residential area and later began to be used also as a burial place.

Cerro Tapera Vázquez (CTV)

The CTV archaeological site is located in the meander plain of El Ceibo stream, inside the Pre-Delta National Park. It is an elliptical mound rising 1 m above the levee adjacent to the stream. In 2008, 16 m^2 were excavated in the highest part of the mound. Its elevation is partly anthropic as a result of accretion of materials during human emplacement (Bonomo et al. 2011b). This occupation extends ca. 100 m along the levee with greater density of materials in the mound, indicating some spatial differentiation of the activities.

The ceramic assemblage shows the predominance of medium- to large-sized open containers with large globular shapes, thin walls, and in some cases closer mouths, smoothed or polished surfaces fired in an oxidizing atmosphere. The recovered items are associated with processing, transport, and/or storage containers. The two- and three-dimensional zoomorphic appendages, decorations with drag-and-jab, a spouted spoon, globular pots with closed mouths, and possible campanas fragments at CTV, together with their ^{14}C age of 520–650 years BP, geographical location, and ecological specificity, all fall within the Goya-Malabrigo entity characteristics. The pottery, with its typical zoomorphic appendages, shows how the animal universe was symbolically and materially incorporated into the cultural sphere of the indigenous populations that lived in the Lower Paraná river.

The site reflects an economy closely associated with the abundant aquatic resources of the Paraná River, including mainly mammals (*Myocastor coypus*, *Hydrochaeris hydrochaeris*, *Blastocerus dichotomus*, and *Ozotoceros bezoarticus*), fishes (Siluriformes and Characiformes), and birds (*Podiceps major* and indeterminate Aves). Archaeobotanical studies made it possible to identify *Phaseolus* sp., *Zea mays*, *Prosopis* cf. *nigra*, *Canna* sp., and Arecaceae. Like numerous sites distributed from the depression of the Salado River in the Pampas to the Humid Chaco, CTV favored the exploitation of coypu. The abundant remains of abandoned coypu with ample evidence of anthropic modification show that site occupation was mainly oriented to the intensive capture, processing, and consumption of this taxon. This orientation toward the exploitation of a given resource makes it possible to integrate the site into a greater settlement system composed of places with different functions, hierarchy, and intensity of occupation. Within this system, CTV would not have functioned as a main residential settlement (village with semipermanent occupation) but rather as a second-order settlement with less intense and recurring occupations.

Laguna de los Gansos 1 and 2 (LDLG1 and 2)

In the archaeological locality Laguna de los Gansos (Diamante, Entre Ríos), an area of 44 m^2 was excavated in LDLG1 and of 16 m^2 in LDLG2. LDLG1 is located in a naturally elevated levee (Bonomo et al. 2016). During its occupation, mainly coypu, capybara, and marsh deer were exploited, and maize was possibly consumed. Ceramic containers of low and open forms predominate, such as plates and medium-sized and small bowls, which indicate they were used for processing and serving food or liquids. The ceramic displays some characteristics similar to those described for Goya-Malabrigo (e.g.,

simply containers, decoration with drag-and-jab, and zoomorphic appendages). In addition to its location in the same levee, LDLG2 shares the exploitation of fauna resources linked to aquatic environments and stylistic ceramic features. It is distinguished by the discovery of human remains that show two clear modes of contemporary burial: primary burial and burial with extraction of the trunk and upper limbs and rearrangement of the skull.

The locality was occupied by populations assigned to Goya-Malabrigo, at least in two different periods. LDLG2 was occupied ca. 600 years ^{14}C BP. Complex mortuary practices were carried out, including dismemberment, selection of parts, and rearrangement of some anatomical sectors of the same individual. This shows that part of the mortuary rituals was based on manipulation of bodies, a tradition shared by different Late Holocene societies of the Paraná River. LDG1 is a succession of shorter occupations on a levee between ca. 1200 and 1800 years ^{14}C BP. It had specific purposes, one of which would have been hunting of large rodents and marsh deer. These sites were occupied only during times with low to medium levels of the river and would have been temporarily occupied and of lower hierarchy than those developed on mound structures located beyond the reach of regular floods.

To sum up, recent research on the mounds of the Upper Delta made it possible to propose the anthropic character of the constructions (Castiñeira et al. 2013; Politis et al. 2011). These constructions were made by populations associated with the Goya-Malabrigo archaeological entity (Ceruti 2003; Politis and Bonomo 2012), whose subsistence was based on the hunting of mammals (coypu, capybara, cavy, and cervids), fishing, and, to a lesser extent, exploitation of birds, reptiles, and freshwater mollusks. This diet was complemented by gathering of wild fruits and cultivation of corn, squash, and beans (Bonomo et al. 2011a; Sánchez et al. 2013; Colobig et al. 2015). The results of our studies (Fig. 9) show the presence in the Paraná Delta of an American widespread complex of seed crops, the corn-bean-squash triad. This confirms the presence of domestic plants among the Goya-Malabrigo populations, although they were traditionally considered hunter-gatherers. It also opens a new horizon of interpretation, as they would not be complex hunter-gatherers but small-scale horticulturists who probably practiced house-garden horticulture. These crops preceded the arrival of the Guaraní in the region, who had been identified as those introducing the crops in the Lower Paraná and Uruguay rivers.

The first European expedition to the Paraná River, undertaken by Sebastián Caboto (1526–1530), described the local indigenous populations (Chaná, Chaná-Timbú, Timbú, Mbegúas, and Carcarais), who would be the sixteenth-century ethnographic expression of the Goya-Malabrigo archaeological entity. The Santa Cruz document, produced during this expedition, illustrates the presence of horticulture and, specifically, the importance of corn sowing and harvesting on the islands during the summer when the river waters were low. Luis Ramírez's famous letter of 1528 shows that other populations besides the Guaraní practiced maize, squash, and bean horticulture.

The information available to date on the Lower Paraná, especially that in early chronicles and, to a lesser extent, in the archaeological record, suggests some level of stable sociopolitical hierarchies, that is, first-order community leadership. Archaeological evidence shows that the burials of some individuals contained pendants and beads made of copper and bronze. The allochthonous nature of the raw materials, the metallurgical techniques, and the designs of these metal ornaments would indicate their Andean origin. Such differential treatment at death could reflect asymmetrical social relations in which some members of the society had unequal access to imported goods from very distant areas, which could have been used to consolidate their prestige and status. In the case of Goya-Malabrigo, special attention was given to the bodies of certain individuals, as shown by one of the secondary burials of La Palmera II site in the Middle Paraná river (Ceruti 2013). The body was accompanied by a varied funerary trousseau (valve collar beads, bone points, zoomorphic appendages, and a

Mound Building, Social Complexity and Horticulture in the Lower Paraná River, Fig. 9 Summary of the identified plants in the Paraná Delta 1. Cerro de las Pajas Blancas 1; 2. Cerro Tapera Vázquez; 3. copper plaque), with possible offerings (an articulated hand and several phalanges), and covered by blocks of sandstone and caliche stone. This complex burial seems to reflect differences according to the status that the person had when alive, as described by some chronicles.

Sixteenth-century chroniclers called the indigenous chiefs of the Lower and Middle Paraná rivers as "mayoral" and "principal." The Spaniards referred to some islands and even some groups by the names of these leaders (used as ethnonyms), which reinforces the idea of formal and permanent leadership. The Spaniards gave European objects to the indigenous chiefs and, in return, received large quantities of corn and fish for several days. This suggests that some of the host leaders controlled some of the resources produced by the community and that they were able to store and redistribute the food. While lax leadership with fragile stability existed, some strong leaders, known for hundreds of kilometers, had some control over fishing and hunting territories.

Serrano (1950: 143) mentions the existence of caciques of greater hierarchy, like Corundá (after whom the Corondás group was named), whose fame of "señor principal" (=main lord) of the coasts of the Parana River reached beyond his territory and was known among the indigenous people of Santiago del Estero. This shows the presence of highly prestigious characters known in a vast region. In some situations, these leaders would confederate to coordinate warlike actions against the Spaniards, which suggests the ability to direct combat and defense operations and to make alliances between politically autonomous units.

It could then be proposed that the non-Guaraní indigenous groups of the Lower and Middle Paraná rivers (those generically called Chaná-Timbú and their predecessors from pre-sixteenth centuries) had a sociopolitical organization that could be included within what is classically known as rank society (Fried 1967). Within such societies, high-rank families or individuals had regular and repetitive authority (albeit weak obedience of their followers); all members of society, be they families or individuals of high rank or not, had guaranteed direct access to the same basic subsistence resources; the division of labor would be primarily based on gender and age, with limited specialization; control of long-distance exchanges and redistribution of the abundant resources and collective products were managed by these leaders or permanent chiefs (see Chapman 2003: 36–37, 85). However, the available information is still insufficient for a more detailed analysis of the level of social inequality of the Paraná River populations.

Summary

The earth mounds of the Lower Paraná and Lower Uruguay rivers are the most visible archaeological features in the contemporary landscape. They are the result of an important investment of human labor, generally on elevated geoforms, which have marked in the cultural topography for two millennia. These widespread architectural structures shaped the landscape of the floodplains of both rivers and were associated with populations differing in their ethnic, economic, and sociopolitical characteristics. Most of the earth mounds have been assigned to the Goya-Malabrigo archaeological entity, although those in the Lower Delta have mainly been attributed to the facie Ibicuí or Ibicueña. The characteristics and sociocultural context of these mounds are different from those of nearby areas such eastern Uruguay and southeastern Brazil, associated with the Vieira Tradition.

These earth mounds had in principle residential and funeral functions and were major settlements within the hierarchy of settlements in the region. The most important ones were probably village loci, while others would have been used for house-garden horticulture. Due to their additive property, once the mounds were constructed by sediment movement, they were permanent, transgenerational, and most of them continued growing as a result of successive occupations. This generated a virtuous circle because once a surface had been raised, it became an attractive space for further human occupations. The sequence elevation-occupation-disposal-abandonment-elevation/conditioning-reoccupation created a structure that increased its height and visibility over time and was transformed into privileged places of the landscape. In addition, these domestic places shared the locus with human burials, linking living groups with their ancestors at specific points of this built landscape. The great complexity with which the dead were treated indicates a significant investment of time and effort in conditioning the remains of the ancestors and shows the central role of ancestry in social reproduction (Goldstein 1995; Budja 2010). In this way, the mounds were signified and re-signified over time and probably constituted places of memory and ancestry. They represented the practical advantage of occupying floodplains and at the same time a space of high social and symbolic value.

Mousterian Industry Tradition

Alvaro Arrizabalaga
Department of Geography, Prehistory and Archaeology, Research Team in Prehistory, University of the Basque Country (UPV-EHU), Vitoria-Gasteiz, Spain

Introduction

Everything about the Neanderthals (and the Mousterian industry which, by definition, defines their tools) arouses great interest among our species. In fact, since the 1980s, the matter of the transition between the last Neanderthals and the first modern humans has generated an unprecedented scientometric concentration (research projects, academic meetings, publications, and excavations). All possible approaches (chronological, geoenvironmental, behavioral, socioeconomic, anthropological, etc.) have been pursued to attain a more nuanced and higher-resolution view, resulting in a history without artificial breaks or divisions, as could only be expected from a historical perspective.

The material culture of our genus clearly evolved over the millennia. Studied by lithic typology in the first place, and by analogous methods (typometric, technological, morphotechnical, and traceology) in later years, this approach has incurred in two main defects. First, it has been too schematic, excessively dividing up a conduct (material), in order to attribute a certain chronology to a certain collection. The second defect is that of particularism, by copying a natural geological concept (the fossil guide) and applying it to human-made objects, which are subject to infinite variability and convergence mechanisms that are inexistent in Nature. These are the circumstances surrounding the casuistry to be described.

Definition

The Mousterian culture, in all its variants, was defined in the late nineteenth century (1872), when Gabriel de Mortillet changed the nomenclature based on the presence of certain animal species in the archaeological record (as proposed by Lartet) into the system followed in geological stratigraphy at that time: an eponymous site displaying the main characteristics of the period was chosen and used as its name. Thus, the cave of Le Moustier (Dordogne, France) was selected as the characteristic site of the Mousterian period.

Since François Bordes (1953) first defined it systematically, Mousterian lithic industry has been characterized by four main factors. First, it developed a series of techniques, which were little used before, for the centripetal removal of blanks, which gave rise to the Mousterian and Levallois cores. In addition, the format of the blanks was very monotonous: a large part of Mousterian assemblages consists of flakes. The same can be said of the retouched assemblages, as a single type, the side scrapers, comprises over half (occasionally over 80%) of the tools. Finally, the character of the Mousterian as a "plateau culture" is quite striking. This refers to the fact that the Mousterian soon differentiated itself from the industrial technocomplexes preceding it, but then did not display a clear evolutionary sequence in

the period, which lasted for between 100,000 and 220,000 years.

About 42,000 years ago in Europe, technocomplexes that steadily differed from the Mousterian and which are attributed to our species began to appear. Over much of the continent, under different forms, the Aurignacian represents the first material culture of anatomically modern humans or "Cro-Magnon Man." In certain areas, like northern Italy, the south of France, or northern Iberia, "transition complexes" (Uluzzian, Chatelperronian, Bachokirian, Szeletian, among others) acted as a link between the end of the Middle Paleolithic (and the Neanderthals) and the start of an unquestionable Upper Paleolithic (and the presence of modern humans). We find, for example, a variable proportion of objects exhibiting certain inertia and which have led to the identification of remains of Mousterian tradition in later phases of prehistoric assemblages. Hence, the main issues associated with the presence of Mousterian tradition industries in more recent times can be summarized as follows: what the effect of the human phyletic change in the material remains fossilized in the archaeological record is, and on an even more basic level, what the mechanisms regulating the transmission of knowledge (including technical knowledge) within preliterate societies are.

Historical Background

Paradoxically, as hunter-gatherer societies are essentially nomadic, the description of Paleolithic groups has been over-static. Progress in the description of the Neanderthal bands who were responsible for Mousterian technocomplexes has been made in parallel, yet without many connections, with the characterization of their Cro-Magnon counterparts. For decades, the dominant methodologies used in the study of the lithic technocomplexes of each species were the systems devised by the husband and wife scholars François and Denise Bordes on common foundations, but without foreseeing any connections or mechanisms of conversion. The question of the chronology of the series being studied was previous to the selection of a determinate methodology; in those cases when it was supposed that it was a Lower or Middle Paleolithic series, the type-list proposed by François Bordes was applied, whereas if it was thought that it belonged to a phase of the Upper Paleolithic, it was studied according to the type-list of Denise de Sonneville-Bordes. In this situation, it is difficult to seek the antecedents of the Upper Paleolithic in the late Mousterian, or the inertia of Mousterian industries in the Early Upper Paleolithic. There is, therefore, a serious methodological issue in this debate, as it has proven necessary to develop new classification and analytical systems to be able to trace the transfer of material knowledge between human groups that even belonged to different species.

The four constants in Mousterian lithic assemblages have been cited above (centripetal reduction techniques, flake production, overrepresentation of side scrapers – the implement of reference – and the long-lasting state of a technocomplex in which it is difficult to distinguish a sequence). Each of these has undergone a differential historical development, within a common historiographical framework where the first typological studies pioneered by Bordes and Bourgon (1951) have been refined by the contribution of technologists (like Boëda, Turq, and Bourguignon) and specialists in raw material procurement (like Geneste and Morala, among others). In this way, if the concept of Mousterian industry was originally linked to its typological characterization (the overabundance of side scrapers, which attracted inordinate classificatory interest), it now possesses an eminently technological definition. Indeed, the vitality of technological studies on the Mousterian has encouraged the French "technological school," which seeks to foster this epistemological approach to Paleolithic societies.

Key Issues/Current Debates

Research on Mousterian industry and its durability in later contexts has advanced notably in the last three decades. Without any doubt, this progress is directly related to the impulse in

technological studies of Paleolithic technocomplexes in Old World schools of thought. European schools, particularly in France, shifted the focus of their research in the last decades of the twentieth century, from typological studies and the interpretation of Mousterian industrial variability to the integral description of the lithic exploitation systems that give rise to lithic technocomplexes.

A first approach to Mousterian industry is concerned with the mechanisms of procurement and selection of the lithic raw material to be worked. Although all predator human societies – whatever the human species – are nomadic and highly mobile, their interaction with lithic raw material varies in time, space, and depending on the species involved. Indeed, throughout the Paleolithic, it is easy to identify a changing selection of the most suitable raw materials (usually with a siliceous matrix, such as flint, quartz, or quartzite), even if it meant transporting it from increasingly distant sources. Thus, human types previous to the Neanderthals used the nearest materials to their settlement and sacrificed the technical versatility of the chosen material to this ease of procurement, with the result of making rougher kinds of implements. Our own species, in the opposite extreme, carefully chose the most appropriate materials to make a wide range of stone tools and weapons, in different formats and with careful details. This obviously implies that frequent journeys had to be made to the outcrops of the best raw materials, where even the form of the material (nodules, blocks, slabs, etc.) and its size were selected to obtain the best product for the kind of exploitation to be applied. In the case of the Mousterian, it corresponds to Neanderthal groups, who lie in an intermediate position between these two extremes. Except for particular cases of proximity or distance from the best raw materials, the geographical range of lithic procurement is intermediate, and the use of local raw materials, of poorer quality, to shape large multipurpose tools was often combined with the transport of high-quality materials to make certain implements, such as the Mousterian points. Therefore, it cannot be claimed (as has sometimes been argued) that strategic and selective procurement of raw materials did not exist in the Mousterian. Furthermore, taking into account the above point about camps established near or distant from high-quality raw materials, in this variable, it is possible to identify a certain chronological sequence in the behavior of Neanderthals and even the first groups of modern humans in each regional environment.

From a typometric viewpoint, J. G. D. Clark's classic work (World Prehistory) institutionalized a generic classification of prehistoric hunter-gatherer groups according to the predominant form of their stone tools. Mode 1 groups based their lithic industry on large stones that were barely modified. They were gradually replaced by Mode 2 societies in which the generally large tools were shaped by bifacial knapping techniques. The Neanderthal groups being studied here belong within Mode 3, when the lithic assemblages are based on flake blanks, and these were in turn replaced by Mode 4 groups, when blade formats became predominant. In general terms, these modes are equivalent to the Lower Paleolithic (Modes 1 and 2), Middle Paleolithic (Mode 3), and Upper Paleolithic (Mode 4). In addition to the Eurasian Mousterian, Mode 3 also applies to the technocomplexes of the African Middle Stone Age (MSA), which is similar but was not produced by Neanderthal humans, who did not exist in Africa. This very general classification has acquired a symbolic value which needs qualifying: the flake format appeared together with the first human industries, both as a by-product of knapping larger tools and in the use of the edges produced. Similarly, even when blade production became widespread, flakes remained a significant part of lithic assemblages, although the novelty of blades and bladelets tends to receive more attention. The traditional characterization of the Mousterian as a flake industry is therefore not exclusive to this period, as flakes are found in the assemblages of any period and are sometimes the most abundant format type in collections.

The third of the factors allows a better chronocultural discrimination of Mousterian industries and the degree of permeability towards this technical tradition by other technocomplexes. This is a series of methods of lithic exploitation aimed at

the systematic production of flakes, which are linked in a more general way with Mousterian or Mousteroid industries. Thus, in societies with industries attributed to Modes 1 and 2, the presence of flakes is a by-product of knapping larger tools or of unplanned, even anarchic, exploitations with the object of obtaining cutting edges. The most significant conceptual change represented by Mousterian or Mode 3 industries (including the African MSA) is connected with this preplanned reduction of the nodules of raw material and the consequent systematic exploitation of the cores. As a result, this first standardization in reduction methods was deliberately aimed at producing a large number of blanks (which could be used directly or act as preforms for an increasingly wide range of tools). In addition, it should be noted that very old Mousterian varieties with blade reduction methods have recently been described for the northwest of France.

In general terms, the most usual name given to this first planned method of lithic reduction is centripetal knapping. Essentially, one or two parallel planes are defined to work the core, with a circular or subcircular shape. The raw material is worked by centripetal removals, from the outer edge towards the center of the working surface, alternating the removals from each surface when two parallel sides exist. As the core reduction advances, this procedure produces very characteristic core shapes, called "tortoise shell" pyramidal or bipyramidal forms. This "Mousterian technique" used this way of working in a generic way, and it thus represents a substantial change in comparison with the anarchic exploitation in the Lower Paleolithic. However, since the beginnings of prehistoric research, a very specific centripetal reduction method has been identified as the "Levallois technique." This technique, originally erroneously associated with a culture (Levalloisian), is one of the most sophisticated forms of lithic reduction practiced in Prehistory and is still difficult to replicate in experimental archaeology. It is a particular form of centripetal reduction in which the shape and size of the blanks to be removed are predetermined. After carefully preparing a striking platform at one of the ends of the centripetal extraction plane, two parallel and convergent extractions are removed to determine a central arris that will guide the symmetry of later extractions (flakes, blades, and, above all, Levallois points, which can be used as spear points with hardly any modifications). The characterization of the Levallois technique experienced rapid progress in the 1980 and 1990s, with the research of E. Boëda (1994) especially, later refined by L. Bourguignon (1999), which has succeeded in identifying the great variability within the technique (Erin and Lycett 2012). From the geographical viewpoint, the distribution of this technique is comparable to that of Neanderthal humans and the Mousterian, basically in Eurasia. However, from the chronological point of view, the different varieties of the Levallois technique extend beyond the lower and upper limits of the Mousterian, from about 300,000 years ago to the Gravettian complex. In short, as has occurred with the evolving definition of the Mousterian and other technical traditions linked with it since the nineteenth century, like the Tayacian, increasing knowledge in recent decades has produced a richer and more nuanced understanding, with greater internal variability and flexibility of previous overrigid spatial and temporal frameworks.

Within the characterization of the Mousterian, the typological factor has traditionally been studied most. Unlike the situation in the much shorter Upper Paleolithic, whose typological diversification has allowed internal systematization since the first research in the nineteenth century, the material monotony of the Mousterian has been an obstacle hindering all attempts at organizing the period. A single tool type (side scrapers) always accounts for the majority of the retouched stone tools, sometimes amounting to over 80% of the total. Other types are found with the side scrapers, like denticulates, simple retouched points, backed knives and objects continuing from earlier periods (trihedrals, bifaces, cleavers, etc.), as well as tools that would become more frequent in later stages (truncated pieces, perforators, end scrapers, and a few burins). Due to the great numerical weight of side scrapers, several attempts have been made at classifying them according to their morphological

appearance, as a way to achieve an internal logic to so many millennia of typological monotony. In the end, proposals attributing a certain chronology to a certain variety of side scraper have been unsuccessful, just as a later attempt to give chronological meaning to the so-called facies ended in failure. Indeed, François Bordes identified several varieties or facies of the Mousterian, depending on the types used, the percentages in which they appeared, or the presence of the Levallois technique: Typical Mousterian, Mousterian of Acheulian tradition (subtypes A and B), Denticulate Mousterian, and Charentian Mousterian (La Quina and Ferrassie varieties), among other proposals that were put forward in the 1960s and 1970s. The failure in the translation of the Mousterian facies, first in chronological terms (Bordes) and then in functional terms (Binford), marked the end of the typological cycle in Mousterian studies, which was definitively replaced by the technological approach. Many of the aspects that had previously been studied through typology, such as Quina side scrapers, Tayac types, and the Levallois concept itself, were now given an exclusively technological consideration.

The above description is an account of Mousterian industrial tradition. Another extrinsic factor is related with the homogeneity exhibited by this tradition for over 200,000 years. Neither the change in perspective involved in replacing typology with technology nor the introduction of absolute dating procedures that cover the chronological range of the Mousterian (unlike radiocarbon dating) has achieved an internal systematization of the Mousterian. Although great progress has been made in understanding the internal diversity of the Mousterian, which now encompasses a much larger chronological range than previously thought, the concept of a "plateau culture" created by the Neanderthals, with hardly any internal evolution and with no temporal sequencing, must be maintained at the present time.

International Perspectives

The geographical distribution of archaeological deposits belonging to the Mousterian culture is concentrated in Europe and central Asia, with a high density of sites in the Near East. The distribution of researchers and research centers is not arbitrary either. Although numerous American researchers have recently started to investigate this period, the main schools of thought publishing about the Mousterian are still in Europe and the Near East. This circumstance has produced certain inertia in the lines of thought going back to the late twentieth century. A frequent approach studied during the last 30 years is concerned with the transition from the Middle to the Upper Paleolithic, the end of the Neanderthals, and the expansion of the Cro-Magnons across the Old World. Since the discovery of a Neanderthal individual in a Chatelperronian level in the cave of Saint-Césaire (Charente, France), the traditional concepts maintained about this phase have been questioned. Each of the changes implicated in this transition (which has come to be known as the Transition, with a capital letter) has been exhaustively reappraised, from the anthropological change to the transformation in symbolic behavior, including the material aspect. The sequence of the variables mentioned above (the raw material used, the increase in the use of blades, changes in technological reduction methods, the introduction of Upper Paleolithic typological elements) and above all the rate and ways in which these changes took place have been the cause of an enriching debate, with countless nuances and references in the literature. The regions where most debate has been generated, as they posses very varied portions of the record, are in the center and east of France, the north of Spain, the Swabia (on the border between Germany and Switzerland), northern Italy, and the Near East.

Future Directions

In the light of this debate on the archaeological understanding of transitions and the creation of a specific commission in the IUPPS about this topic (Camps and Chauhan 2009), in coming decades, detailed regional knowledge will be attained about the circumstances of the transition in each area. Although Paleolithic human societies were

nomadic, they are described in a paradoxically static way, based on the description of a single site or several contemporary deposits, in a single regional environment. The fact that the objective of Prehistory is to obtain an understanding of historical processes from a record with geological resolution does not help in acquiring a precise view of complex underlying cultural phenomena. The material record, due to its archaeological characteristics (it is conserved relatively well and abundant at most sites, its techno-typological evolution is known, and a tested geochronological framework is associated with it), is especially appropriate for a more dynamic reconstruction, in terms of the introduction of innovations and the persistence of industrial traditions in later phases. Future decades will doubtlessly see conflicting information, contradictory with what are regarded as certainties today. However, progress in the knowledge of Prehistory, as in many other scientific disciplines, often comes from situations of crisis, their solution, and the new epistemological and methodological approaches introduced during the whole process.

Movius Line

Fumiko Ikawa-Smith
Department of Anthropology, McGill University, Montreal, QC, Canada

Introduction

Over 70 years ago, Hallam L. Movius, Jr. (1907–87), in the first major synthesis of early Paleolithic materials from East and Southeast Asia (Movius 1943, 1944, 1949), observed that the stone implements that were being recovered from Pleistocene deposits from the area were very different from those that had been known from the deposits of similar ages elsewhere in the Old World. The line that marked the boundary of the eastern and western cultural complexes during the early prehistoric times came to be known as the Movius Line, and probable causes for the difference, as well as the existence of the demarcation line itself, have been the topic of debate over the decades, particularly in recent decades, as new archaeological, geochronological, and chronometric data are brought to light and interpretations from different perspectives are being offered.

Definition

The Movius Line, running across northern India, delineates the area characterized by what Movius called "Chopper/Chopping-tool Culture" from the "Hand-axe Culture" area to the west (See Fig. 1). On his return from the field research in Burma and Java with the Joint American Southeast Asiatic Expedition for Early Man, 1937–1938, Movius found it necessary to formulate a new typological scheme in order to describe the artifacts of the newly found assemblages. He offered the following terms, emphasizing, as he did on many occasions since, that these categories are based on the form and the technique of manufacture only, without implying the possible function of the implements (Movius 1943: 350–353, See Fig. 2):

(a) *Choppers*: Tools with round, semioval, or almost straight cutting edges which have been formed by the removal of flakes on the upper surface of the implement only in most cases, although some are flaked on the lower surface as well.
(b) *Chopping-tools*: Bifacial core implements, usually made on pebbles, with sinuous cutting edge produced by alternate flaking.
(c) *Hand adzes*: Unifacial implements of roughly tabular form, with slightly rounded or even a pointed cutting edge, which forms a right angle with the long axis of the implement.
(d) Scrapers: Smaller version of choppers that are made on cores or flakes.

In the more comprehensive syntheses of the early prehistoric assemblages from South and East Asia as a whole, the choppers and the scrapers, which were distinguished by the size difference, were collapsed into one category of *Choppers and/or Scrapers,* while a new category of "Proto-hand-axes" was added to accommodate the artifacts recovered from Patjitan in Java (Movius 1944: 91–92, 1949: 350; See Fig. 2: no.4).

(e) *Proto-hand-axes*: Crude and roughly pointed or oval types of hand adzes of plano-convex section, worked on the upper surface only, leaving large areas of cortex at the butt ends. Typologically transitional between hand-adzes and true hand-axes.

As of the late 1940s when the concept was proposed, the components of the Chopper/Chopping-tool Culture (or Chopper/Chopping-tool Complex, as he uses the terms interchangeably even in the same publication, e.g., Movius 1949: 408, 409) were the Soan (sometimes spelt "Sohan") of the Siwalik Hills region of the Indian subcontinent, the Anyathian of Burma (now Myanmar), Tampanian of the Malay Peninsula, the Patjitanian (now called Pacitan) of Java, and the Choukoutienian (now spelt Zhoukoudian) of North China (see Map on Fig. 1). As Movius frequently emphasized (e.g., Movius 1944: 103, 1949: 408), the area of the Chopper/Chopping-tool Culture is distinguished from the

Movius Line, Fig. 1 Distribution of Hand-axes Culture and the Chopping Tools Culture during the Middle Pleistocene, as presented by Movius (1949: 409)

Hand-axe Culture area of the west, not only by the presence of the categories of stone tools mentioned above but also by the absence of the fully bifacial Acheulean-type hand-axes and the Levallois method of flake detachment that characterize the Lower and Middle Paleolithic of Africa and western Eurasia. The area east of the Movius Line was depicted as being culturally homogeneous, with little change over a long period.

It should be noted that, while the concept of the "Chopper/Chopping-tool Complex," as well as Movius's definitions of tool-types such as the "hand-adze," were being widely accepted through the 1940s and 1950s, it was not until 1965 when the dividing line was given the name. It appears that the name originated with Carleton S. Coon (1904–1981), in his controversial book on race, where he stated: "during the Pleistocene the inhabited parts of the Old World were divided into two archaeological regions, a western and an eastern one, by a geographic frontier that we shall call Movius's Line, after its discoverer" (Coon 1965: 47–48). In recent

Movius Line, Fig. 2 Major Components of the Chopper/Chopping-Tool Culture after Movius (1949: 351)

years, most authors refer to the line as "Movius Line" (e.g., Dennell 2009; Keats 2002; Lycett and Bae 2010; Schick 1994) without the "apostrophe S."

Key Issues/Current Debates

In his expanded treatise on the Lower Paleolithic of the region, Movius (1949: 410) observed that

pebble tools appear to have been present as the "basic cultural substratum" in many parts of the Old World, before the development of the fully bifacial Acheulean hand-axes, but the latter did not appear in the region under consideration.

Then, he concluded the monograph with the statement:

> Perhaps the most important single conclusion to be drawn from the implications of the new archaeological material brought to light during the last fifteen years in Southern and Eastern Asia is that this area cannot be considered in any sense 'progressive' from a cultural point of view... In other words, the archaeological, or palaeo-ethnological, material very definitely indicates that as early as Lower Palaeolithic times Southern and Eastern Asia as a whole was a region of cultural retardation. Therefore, it seems very unlikely that this vast area could ever have played a vital and dynamic role in early human evolution, although very primitive forms of Early Man apparently persisted there long after types at a comparable stage of physical evolution had become extinct elsewhere. (Movius 1949: 411).

Many readers, including the emerging generation of Asian scholars who were now frontline practitioners investigating the archaeological heritage of their own countries, found this characterization of the area objectionable, particularly with the phrase "as early as Lower Palaeolithic times," which implied that it is still "culturally retarded." Linking the cultural retardation to the presence of "primitive" forms of humans was taken to indicate racism. A few years later, however, Movius modified his view as follows:

> "...it is very much more likely that this occurred because of a failure of more advanced techniques to diffuse into the area than because the primitive types of mankind who lived there during Middle Pleistocene times were incapable of understanding the new and improved methods that had been and were being developed elsewhere in the Old World...." (Movius 1953: 189).

To paraphrase this observation in current terminology, a widespread dispersal of the Oldowan tool complex or the Mode I technology of Clark (1969) was followed in Africa, Europe, and western and southern Asia by Mode II technology with Acheulian toolkit containing fully bifacial hand-axes and cleavers, but the Mode II technology failed to reach east of the Movius Line. Although the allusion to cognitive incompetence due to biological limitation was removed, the image of the region as cultural backwaters, isolated from the centers of cultural innovation, remained.

As the pace of archaeological research picked up and flow of information improved in postwar Asia, bifacial tools were reported from several sites, such as Dingcun (formerly spelt "Ting-Ts'un") (Aigner 1978; Pei et al. 1958), and Kehe (also spelt "K'oho") (Chia et al. 1962) in China, Mount Yarkh in Mongolia (Okladnikov 1978), Gongenyama in Japan (Maringer 1956), and Mount Do in Vietnam (Boriskovsky 1978) (Fig. 3). These findings, particularly the recovery of bifacial artifacts in Chongok-ni (also spelt as "Chongok-ri" and "Jeon-gok-ri") in Korea starting in 1978 (Kim and Bae 1983), led some authors to recommend that the concept of the Movius Line be abandoned. For example, Yi and Clarke (1983: 190) stated: "Movius's simplistic classificatory scheme for Asian Palaeolithic should be discarded, for it ignores the very real complexity of the Palaeolithic of the area."

Is the Movius Line Still Valid?

Bifacially prepared large cutting tools continue to be reported from various parts of East Asia. Particularly noteworthy is a series of discoveries in recent years of clusters of sites where sizable numbers of bifaces were recovered. The clusters are located in the Bose (also spelt "Baise") Basin in Southern China (Hou et al. 2000; Wang et al. 2014), the Luonan Basin in Central China (Wang 2005), the Imjin-Hantam River Basin on the Korean Peninsula (Norton et al. 2006), and various locations in the island chain of Indonesia, including Sangiran in Java and along the Ogan River in southern Sumatra (Fig. 3). The Bose artifacts are described as being "Acheulean-like" (Hou et al. 2000), while the Luonan specimens are reported to fit "comfortably within the Acheulean range of variation" (Petraglia and Shipton 2008: 965), and the bifacial tools from Indonesia are seen as the evidence for "the arrival of typical Acheulean technology" around 0.8 million years ago in Indonesia, where it coexisted, perhaps

Movius Line,
Fig. 3 Archaeological Sites Mentioned in the Text. *1* Bose Basin, *2* Chongok-ri, *3* Dingcun, *4* Gongenyama, *5* Imjin/Hantan Basin, *6* Kehe, *7* Luonan Basin, *8* Mount Do, *9* Mount Yarkh, *10* Ogan River, *11* Pacitan, *12* Sangiran, *13* Zhoukoudian

briefly, with the pebble tool tradition (Simanjuntak et al. 2010: 421).

The situation is clearly far more complex than what Movius depicted over 70 years ago. The cultural landscape is certainly not homogenous nor is it monotonously unchanging. Nevertheless, a number of authors expressed the view that "the Movius Line remains a useful demarcating line between those regions of Asia and Europe where bifaces were commonly used, and those where they were not (e.g., Dennell 2009: 434; Schick 1994; Keats 2002). In proposing a concept of "Movius Line sensu lato," Norton et al. (2006: 534) observed the following:

1. Compared to East Africa and India, the frequency of hand-axes sites in East Asia is significantly lower.

2. The percentage of bifaces in the East Asian assemblages is usually much lower than coeval sites in India and East Africa.
3. East Asian hand-axes are morphologically different from those in the west (they are thicker, often with a plano-convex cross section).

Explanations for the Movius Line

If the Movius Line, even in a somewhat modified sense, is still a viable concept, what is/are the reason(s) for its existence? Possible factors considered by various researchers include the following:

1. **The limitations placed by the nature of the available lithic material**

This was one of the factors Movius himself mentioned as a possible reason why the fully bifacial hand-axes and the Levallois technique of flake production were absent from the area, but his position appears to shift over the years (e.g., Movius 1943: 376, 1944: 75–76). In his last statement on the question, he stated that it was not the determining factor because "even in cases where flint was available, the typology of the artifacts inevitably remained within the strictures of the general pebble tool category" (Movius 1978: 354). Indeed, Schick (1994: 589) shows a thin, well-prepared hand-axe she manufactured from a piece of tabular limestone, found near the Zhoukoudian site, well-known for the choppers, chopping tools, and simple flake tools made of quartz and quartzite.

On the other hand, Leng and Shannon (2000), based on detailed examination of artifacts and replication experiments using the same lithic materials as the archaeological specimens at five Chinese and three Indian sites, state that the raw material can strongly affect the typology of the end product. They note also that producing tools from brittle and junctured quartzite is just as cognitively challenging as producing a symmetrical straight edge out of uniformly structured chert.

2. **Barriers to migration and cultural diffusion**

As noted above, Movius (1953: 189) suggested that the chopper/chopping-tool tradition persisted because of "a failure of more advanced techniques to diffuse into the area" without specifying what may have caused it. Recent reviews (e.g., Dennell 2009; Lycett and Bae 2010) considered the possibility that the Himalayan mountain range; Qinghai-Tibetan Plateau; the major river systems like the Ganges-Brahmaputra, the Irrawaddy, and the Mekong; and the tropical rain forests may have acted as barriers for human movement and cultural transmission. Lycett and Bae (2010: 527) conclude, however, that with the exception of the Himalayan and Qinghai-Tibetan Plateau, which were not penetrated until the latter part of the Late Pleistocene, the geographic and topographic barriers do not appear to provide a full explanation for the Movius Line.

3. **Alternative non-lithic raw material (bamboo) and importance of flakes**

It has been suggested by a number of researchers that the reason why the early inhabitants in the area east of the Movius Line did not expend much time and efforts in manufacturing bifacially prepared tools was the presence of alternative non-lithic raw materials, such as bamboo, which could serve as cutting tools, as well as containers, and has the advantage of being lightweight for carrying during long foraging trips. Pope (1989) has demonstrated the overlap of the distribution of bamboo in eastern Asia with the Movius' Chopper/Chopping-tool Culture area. Schick (1994: 591) illustrates how a piece of split bamboo can serve as a very effective butchering tool and notes that bamboo can be easily worked with simple stone tools.

In this connection, it should be pointed out that Movius' Chopper/Chopping-tool Complex overemphasizes the core tools, when in fact the toolkit is characterized by the dominance of small flakes. It has been argued that it is the flakes struck-off pebble cores, used as expedient tools to make the real primary tools out of such organic

materials as bamboo, that characterized the early Paleolithic assemblages of East and Southeast Asia (Ikawa-Smith 1978).

Unfortunately, the perishable nature of the non-lithic materials preclude the survival of actual evidence. One hopeful indication is the report that a scanning electron microscope examination revealed morphological differences in the cut marks experimentally produced on mammalian bones by bamboo knives from those produced by chert blades (West and Louys 2007). The authors state, however, that marks made by bamboo knives tend to be shallow, thus are likely to fade more easily than those made by stone tools. Nevertheless, it opens a possibility to confirm the "bamboo hypothesis," if and when a zooarchaeological specimen with cut marks that match the tell-tale morphological characteristics of the marks made by bamboo knives.

4. **Demography and transmission of technical knowledge**

The last possible reason for the Movius Line to be considered here is the difficulty for a group of sparsely distributed mobile hominids to maintain a set of complex technical knowledge such as Acheulean toolmaking technology. Schick (1994: 590) notes that as a group of hominids moved into a new area, they may face problems such as locating the lithic materials suitable for biface production, and it may take many years or even a generation before such a material is located. In the meantime, they would have made simpler tools using locally available materials, and the transmission of the technical knowledge would have been interrupted, and the technological tradition could eventually be lost.

Lycett and Norton (2010), in their demographic model to account for the Movius Line, suggest that the thick hand-axes that have been recovered from East Asian sites are the results of convergence with the Acheulean development elsewhere, not the result of intrusion from the west. Hand-axes may have been manufactured in several places in eastern and southeastern Asia for short periods of time, but production did not continue, in their view, because of the demographic conditions: the population density was low, with a small number of skilled practitioners, and the opportunities of sociocultural interaction and transmission of knowledge would have been limited.

Current State and Future Directions of Research

In one of his last statements on the subject, Movius (1978: 354) stated that "[t]he underlying reasons for this remarkable conservatism still remain unfathomed." Sixteen years later, Schick (1994: 591) echoed the sentiment by subtitling the concluding section of her chapter on the Movius Line as "The Movius Line is still a paradox." After decades of debate and a series of recent discoveries, opinions are still divided as to the validity and/or usefulness of the Movius Line. On the one hand are those who advocate discarding the concept (e.g., Bar-Yosef and Wang 2012), while on the other are those who favor keeping it in order to test its validity (e.g., Wang et al. 2014). With the increasing number of new finds, additional chronometric dates and geochronological observations, and adoption of new theoretical perspectives, however, we have also seen some researchers who have change their opinions in recent years. Most remarkable reversal of the view that came to this writer's attention is the recent statement by Dennell (2016), who, contrary to his position in 2009 (see above), now states that "the Movius Line is no longer an appropriate way of studying the Early Palaeolithic of East and Southeast Asia, and should be disregarded."

Dennell (2016) elucidates his reasons for his new position in the following way: (1) Fossil records indicate that China during the Middle Pleistocene was not as isolated from the rest of Eurasia as has been suggested. It is therefore possible that dispersal of hominins from west to east or vice versa could have taken place. (2) The definition of "Acheulean" is no longer clear, and, in any event, the proportion of biface in an assemblage vary greatly in in Africa and western

Eurasia as it does in East Asia. (3) Bifacial hand-axes were absent from Zhoukoudian assemblages because they are in caves, as they are rare in cave sites elsewhere as well. And finally (4) none of the assemblages in south and southeastern Asia Movius named in his original formulation of the "Chopper-Chopping Tool Culture" area (see Fig. 1) is contemporaneous with the Middle Pleistocene Acheulean assemblages elsewhere.

Efforts will continue to be made to increase quantitative data comparing morphology of bifaces from both sides of the Movius Line. Efforts will also be directed to obtain more precise dates on relevant assemblages, those containing "Acheulean-like" bifacial elements as well as those consisting only of core and flake tools. Many of the early Paleolithic artifacts have been collected from the surface and remain undated. Even when chronometric dates are available, there often are questions concerning the relationship of the artifacts to the dated samples. Reliable dates, matched with quantitative data on assemblage composition and artifact morphology, will contribute toward gaining a perspective on the patterns of appearance of bifaces in eastern Asia, in relation to the simpler core and flake tools. When compared with the patterns of temporal and spatial distribution and the characteristic shapes of the bifacial artifacts elsewhere, particularly in southwestern Asia and Indian subcontinent, the distribution patterns may clarify one of the outstanding issues: Was the eastern hand-axe indigenous or the result of diffusion from the west? If they are brought in from the west, when did it happen?

Experimental replication of artifacts, cut mark analyses, and paleoenvironmental studies will also be pursued, as will further inquiries into paleodemography. When suitable human fossils are found, and DNA could be extracted, we might learn something about the biological affinities of the ancient toolmakers. In short, a well-coordinated multidisciplinary approach would help toward solving the "paradox" of the Movius Line.

Movius, Jr., Hallam L.

Philip E. L. Smith
Montreal, QC, Canada

Basic Biographical Information

Hallam L. Movius, Jr. was born in Newton, Massachusetts, in 1907 and educated at Harvard University. He was appointed as a tenured professor of anthropology at Harvard in 1950 and was also curator of Paleolithic archaeology in the Peabody Museum of Archaeology and Ethnology. He retired from teaching in 1974 and from his curatorship in 1976. He died at home in Holyoke, Massachusetts, on 30 May 1987.

Major Accomplishments

For many years, Movius was considered the dean of Paleolithic studies in the United States. Not the first American to work in the Paleolithic (Homer Kidder, Harper Kelley, and Alonzo Pond preceded him), he was certainly the most influential and productive for several decades from the late 1930s onward. He established it firmly as a discipline in a major university, and he was the dominant figure in undertaking fieldwork, training graduate students, and creating broad regional and interregional syntheses. During those years, he made the Peabody Museum one of the world's focal points for Paleolithic research.

As a young man he seemed destined for a career in finance or business like his father. While an undergraduate at Harvard from 1926 to 1930 he developed a strong interest in archaeology and especially Old World prehistory. His first fieldwork was at the Neolithic site of Homolka in Czechoslovakia in 1930. In 1932, he participated in Dorothy Garrod's investigations at Mugharet es-Skhul in Palestine. From 1932 to 1936, he was in Ireland as a member of a Harvard expedition, excavating a number of Late Mesolithic and Early Neolithic sites around the island. These were the basis for his 1937 doctoral dissertation. In 1937, he briefly abandoned European prehistory to join an international expedition in East Asia. With Helmut de Terra and Pierre Teilhard de Chardin, he spent 4 months in the field in Burma. Following this, he visited Java to inspect Paleolithic sites and artifacts under the guidance of G. H. R. Von Koenigswald. The research produced several monographs on the Early Paleolithic of South and East Asia that were remarkable syntheses of archaeological, geological, and paleontological data extending from India to China and the East Indies, with tentative interregional correlations and interpretations and an innovative lithic

terminology defining the great chopper-chopping-tool complex (Movius 1948).

He is probably best remembered today for his work in East Asia, but he chose not to return there after 1938. From 1942 to 1946, he served in the US Army Air Corps as an intelligence officer overseas. After discharge, he resumed his duties at Harvard as a teacher and curator. His research interests now lay in the Upper Paleolithic of Western Europe, particularly France. He excavated the site of La Colombière in eastern France in 1948, where his discovery of an "Upper Perigordian" engraved pebble spurred a lasting interest in Paleolithic art. He was intrigued by the controversy over the so-called Aurignacian-Perigordian dichotomy in southwestern France and decided to evaluate the hypothesis through new fieldwork. From 1958 to 1964, he excavated the deep stratified rockshelter of Abri Pataud in Les Eyzies, Dordogne, and the analysis and publication of the results occupied him for the rest of his active professional life (Movius 1974). He continued to work after suffering a stroke in 1970 but in his last years was virtually incapacitated.

Movius saw as one of his responsibilities making the results of Paleolithic research available to the international scholarly community. He had a large network of correspondents around the world, in Europe, Africa, and Asia who kept him informed of their investigations and sent him their publications. He encouraged the translation and publication of reports written in Russian, Chinese, and Japanese that were virtually unknown in the West. In 1952, he prepared a far-ranging synthesis of the state of Paleolithic research for an international symposium in New York (Movius 1953). Not the least of the contributions of this article was introducing to English-speaking scholars the recent technological studies and quantitative methods of the young French prehistorian François Bordes.

In the early years of radiocarbon dating, he operated a kind of international clearing house for the new method and undertook to accept Paleolithic charcoal samples from colleagues overseas without access to radiocarbon facilities which were then analyzed in American laboratories.

Movius' research was characterized by meticulous, intensely focussed work. From his days in Ireland, he had strongly emphasized the necessity of interdisciplinary research, studying archaeological remains in their environmental and ecological contexts, and he continued this approach in France. In the 1950s, he was greatly impressed by the work of Grahame Clark and André Leroi-Gourhan in exposing living surfaces and activity areas. He attempted this at Abri Pataud while simultaneously paying careful attention to the complex stratigraphy of the site as he unraveled the relationships between the 14 or so cultural levels from the Early Aurignacian to the Solutrean. His interpretation of the Aurignacian and other hearths illustrates his growing interest in what some call social archaeology (Fig. 1).

It cannot be said that he created a school or even a band of disciples with a specific orientation. One reason may be that he rarely made specific statements about his own methodological and theoretical principles. He usually preferred to leave them implicit in his published work rather than spell them out. Movius did not enjoy professional controversies and disputes. In the face of criticisms, he preferred a dignified silence rather than defense or counterattack. This may account

Movius, Jr., Hallam L., Fig. 1 Photograph of Hallam Movius at Abri Pataud in 1958 with students

for the absence of direct responses to the charges made by some authors against his interpretation of the apparently long period of lithic artifactual stasis in Asia, east of the "Movius Line." While in 1948, he had used language suggesting the area had been unprogressive and even culturally retarded, in his 1953 paper, he rejected explanations based on biological or cultural inadequacy. Given his deeply conservative temperament and humanistic outlook, his depiction of a long, separate, and relatively unchanging regional lithic tradition may be viewed as consonant with his own innate devotion to stability and continuity.

Muckelroy, Keith (Extreme Environments)

Matthew Harpster
Department of Archaeology and the History of Art, Koç University, Istanbul, Turkey
Institute of Nautical Archaeology, College Station, TX, USA

Basic Biographical Information

Born: September 6, 1951; Died: September 8, 1980.

Keith Muckelroy earned his undergraduate degree at the University of Cambridge in 1974 under the tutelage of Grahame Clark and David Clarke. While there, he learned to dive with the Cambridge University Underwater Exploration Group (CUUEG) and became involved in the excavation of the seventeenth-century Dutch East Indiaman *Kennemerland*, which had wrecked in the Out Skerries, Shetland, in 1664. Following graduation, he began an assistantship in maritime archaeology under Colin Martin at the newly formed Institute of Maritime Archaeology at the University of St. Andrews, in Scotland. Over the following six years, Muckelroy continued working at the excavation of *Kennemerland* while leading other expeditions in England and Greece and began a new position as the Archaeologist Diver in the National Maritime Museum's Archaeological Research Centre in Greenwich, England. By 1978, he had returned to Cambridge to begin his doctoral research, preliminarily titled "Site Analysis and Maritime Archaeology"; had published additional articles in *The International Journal of Nautical Archaeology*, *World Archaeology*, *Britannia*, and *Progress in Underwater Science*; and finished his first book, *Maritime Archaeology* (Daniel 1980). His final two manuscripts, *Archaeology Under Water* and *Discovering a Historic Wreck*, were published following his death in a diving accident in Loch Tay, Scotland.

Major Accomplishments

Muckelroy's interests stretched beyond maritime archaeology, but they focused primarily in the analytical investigation and interpretation of sites under water. This was the subject of his Ph.D. research and many of his publications. His 1975 article in *The International Journal of Nautical Archaeology* applied matrix analysis and numerical taxonomy to the assemblage of *Kennemerland* to determine how much the various classes of artifacts in the assemblage had been scattered by the wrecking process. A 1976 article in *World Archaeology* attempted to codify and to illustrate the different forces transforming a ship into an archaeological assemblage (Fig. 1), whereas two articles published in 1977 used the Kendall ranking coefficient to reveal the relationship between

Muckelroy, Keith (Extreme Environments), Fig. 1 In 1976, Muckelroy published a chart depicting the forces that affect a ship as it sinks and becomes an archaeological site on the seafloor

site cohesion and 11 environmental factors. These studies built the content of the second half of his 1978 book, *Maritime Archaeology*, but they also reveal the influence of Grahame Clark and David Clarke in Muckelroy's thinking. Grahame Clark may have inspired Muckelroy's 1977 articles through a chapter on site preservation in his *Archaeology and Society*. As Clark wrote about different climates, Muckelroy wrote of currents, winds, and waves; as Clark wrote of different soils, Muckelroy wrote of the topography of the seabed and different deposits. Clark's discussion on social behavior on land, then, became salvage operations under water (Clark 1939: 57–85; Daniel 1977a: 112–3, 1977b: 51). In contrast, David Clarke's impact may have been more fundamental. Much of Muckelroy's application of statistical analyses adapted ideas in Clarke's *Analytical Archaeology* and, behind that, the influence of Systems Theory and an emphasis on explicit methodologies characterizing New Archaeology. Moreover, Muckelroy's goals may have emulated Clarke's as well.

Clarke's *Analytical Archaeology* promoted matrix analysis as a central, hierarchical paradigm in archaeology and was, effectively, a guide that other archaeologists could follow. The second half of Muckelroy's *Maritime Archaeology*, titled "Towards a theory of maritime archaeology," similarly creates an interpretive framework to guide maritime archaeologists through their investigations of shipwrecks. This framework was based upon the different techniques tested in his articles published in 1975, 1976 and 1977. As a group, they demonstrate different stages in the process of transforming an assemblage into the ship it represents. The 1977 studies quantify how environmental factors may affect the preservation and distribution of an assemblage, his 1976 article demonstrates how to predict differences between

the content of the assemblage and the content of the original ship, and the 1975 essay proposes how to determine the functions of objects within the assemblage. In short, these articles and Muckelroy's book contain explicit techniques which, when arrayed together, become the essence of a paradigm needed to recreate a ship from the assemblage left on the seafloor.

Keith Muckelroy wrote his articles and books at a time when maritime archaeology was still young, yet no longer a novelty, and its terrestrial predecessor was assimilating the new philosophical and analytical methodologies that had asserted themselves in the previous decade. As a result, Muckelroy's landscape in the United Kingdom and particularly at Cambridge – what he called a "hothouse of academic archaeology" – was a combination of vibrant individuals redefining archaeology in a variety of ways (Daniel 1978: ix). In addition to Grahame Clark and David Clarke, Muckelroy's mentors also included Colin Martin, George Bass, Nicholas Flemming, Robert Yorke, Joan du Plat Taylor, and A.J. Parker. These were people who were developing new methods of gathering archaeological data from new sources in the sea and testing new perspectives on how best to interpret and understand that information. Much of Muckelroy's work demonstrates his attempts to integrate these influences, but due to his early death they reflect only his first attempts to do so. While he was fundamental in demonstrating the potential of applying statistical analysis to the interpretation of sites under water, he did not have a chance to explore its potential to the fullest. As valuable as it is, then, his corpus represents the beginning of years of scholarship, not the end; his plans and vision, then, may only be extracted from the material in hand while their fulfillment lay with his successors.

Muckelroy, Keith (Underwater and Maritime Archaeology)

Paula Martin
Cupar/Fife, Scotland, UK

Basic Biographical Information

Keith Muckelroy (1951–1980) (Fig. 1) studied Archaeology and Anthropology at Jesus College, Cambridge, between 1970 and 1974, achieving a first class degree. He was particularly receptive to the teachings of the prehistorians Grahame Clark and David Clarke and acquired excavation experience on land sites, including Wroxeter. In 1971, he learned to dive with the Cambridge University Underwater Exploration Group. Two years later, as their diving officer, he led an expedition to survey the submerged harbor at Apollonia,

Muckelroy, Keith (Underwater and Maritime Archaeology), Fig. 1 Keith Muckelroy

Libya. Membership of this group of divers from a range of academic disciplines introduced Keith to similar groups from other universities.

In 1971, divers from Aston University had located the Dutch East Indiaman *Kennemerland*, wrecked in 1664 off Out Skerries, Shetland. Keith joined them in 1973, and this scattered site became the main focus for his study of wreck-formation processes. After graduation, he joined Colin Martin in the recently established Institute of Maritime Archaeology at the University of St Andrews, on the east coast of Scotland, and spent summers working with Colin and the author on the wrecks of the *Dartmouth* in the Sound of Mull, Scotland (1690); *El Gran Grifon* off Fair Isle, Scotland (1588); and *La Trinidad Valencera* off Donegal in Ireland (1588). In addition to this, he continued his work on the *Kennemerland* and, as part of a large team, on the *Mary Rose* (1545) excavation.

Keith was a hard worker, dedicated to his subject, but easy to work with. He was able to combine the practical side of diving with high-caliber field archaeology and to engage in debate and theorizing. He had very clear views on ethics and deplored the argument – widely advocated in some quarters during the 1970s – that archaeologists could work with treasure hunters. Those of us who knew him and worked with him sometimes teased him for his single-mindedness, but he had a very human side too, and we all miss him and still wonder how his ideas and career might have developed.

Major Accomplishments

"Between his graduation from Cambridge University in 1974 and his death in 1980, Keith Muckelroy's work and ideology were crucial in promoting an alternative research methodology in maritime archaeology" (Harpster 2009: 67). In this early period of the development of maritime archaeology, it was unusual for someone to enter it from a standard archaeological background, rather than from a sense of adventure, a love of diving, or a love of boats.

Between 1975 and 1978, he published seven articles in academic journals. His first book, *Maritime Archaeology*, published in 1978, has since achieved seminal status. He also became involved in work on two underwater finds of Bronze Age material off the south coast of England. So within a few years, he managed to gain experience of quite a number and wide range of sites. In 1977, he left St Andrews and returned to Cambridge to work towards a Ph.D. on "Aspects of Maritime Archaeology, with Special Reference to Cross-Channel Contacts in the Later Bronze Age." In 1980, he joined the Archaeological Research Centre at the National Maritime Museum in Greenwich, but in September 1980, while working on the excavation of a crannog in Loch Tay, Scotland, he was drowned.

Students still discuss Muckelroy's ideas, and some have tried to produce a sequel to his published work or further develop his ideas, but none has yet fully succeeded. Subsequent generations of students in the UK have not yet produced a maritime archaeologist of similar caliber, breadth of interest, and single-minded determination. "In the ten years since he learned to dive as an undergraduate . . . he had achieved more than

many achieve in four decades of a working life" (McGrail 1980).

Muke, John

Tim Denham
Archaeological Science Programs, School of Archaeology and Anthropology, ANU College of Arts and Social Sciences, The Australian National University, Canberra, ACT, Australia

Basic Biographical Information

John Muke (1960–) is a member of the Tangilka tribe from Tumba in the Middle Wahgi Valley of the highlands of Papua New Guinea. As well as being a prominent archaeologist within Papua New Guinea, John is also required to fulfil the traditional role of a "big man" within his community.

John went from Mount Hagen High School to the University of Papua New Guinea (UPNG), Port Moresby, in 1979. He subsequently obtained his Bachelor of Arts in 1982, specializing in archaeology under the tutelage of Professor Les Groube. He continued his archaeological studies, specializing in research on waisted blades, at the Australian National University for a Bachelor of Literature (B. Litt.) between 1982 and 1985 (Muke 1984).

In 1985, John began his Ph.D. in ethnoarchaeology at Cambridge University under the supervision of Professor Ian Hodder. John's Ph.D. research marked a dramatic departure from his previous, more conventional archaeological studies and drew heavily upon his own experiences of warfare in the Wahgi Valley (Muke 1992). Following completion of his Ph.D., John returned to Papua New Guinea to take up a lecturing position within the Department of Anthropology and Sociology at UPNG.

Between the late 1990s and early 2000s, John transitioned from being an academic archaeologist at UPNG to becoming a consultant in a range of cultural, economic, and social fields. Consultancy projects included water usage/provision and poverty alleviation for squatter settlements in Port Moresby and the prevention of HIV/AIDS in the Wahgi Valley. At the same time, he maintained an active interest in, and was an advocate for, cultural heritage at Kuk and elsewhere in the country (Muke 1998, 2000). From around 2005, John's consultancy – Social Research Institute – has focussed more heavily on cultural resource management projects in the country, most of which are associated with large, resource extraction developments.

Major Accomplishments

John's B.Litt. studies on waisted blades continued research begun with Les Groube on this distinctive type of stone axe-adze found across New

Guinea, as well as in Australia and elsewhere. Waisted blades are generally associated with the Pleistocene, although they have also been reported from Holocene contexts on New Guinea (Bulmer 2005). At the time, waisted blades found on the Huon Peninsula marked the (then) earliest evidence for the presence of humans on the island of New Guinea around 40,000 years ago (Groube et al. 1986).

While lecturing at UPNG, John embarked on new archaeological investigations in the highlands, which provided an opportunity to train a new generation of archaeologists. For example, in 1993 and 1994, he directed wetland archaeological investigations at a newly drained coffee plantation at Kana, Middle Wahgi Valley (Muke and Mandui 2003). Archaeological finds at Kana suggested several episodes of drainage for cultivation extending back to c. 3000 years ago, including evidence for the cultivation of wax gourd (*Benincasa hispida*) 3000–2000 years ago. During this time, John maintained regular contact with the Kawelka at Kuk Swamp in the Upper Wahgi Valley in order to monitor the site following reoccupation by traditional landholders (Muke 1998).

In 2006, John volunteered to codirect (with myself) the completion of the World Heritage nomination for the Kuk Swamp site in the Upper Wahgi Valley. John's role, together with that of his long-term friend and colleague Jo Mangi, was to complete the traditional land-use management plan for the site, which would be a world-first for a World Heritage Site (Muke et al. 2007). John's long association with the Kawelka at Kuk was important to the successful inscription of Kuk in 2008 and ongoing management of the site. Although the management plan for Kuk only exists in draft form, it incorporates traditional community social structures, land-use practices, and values that enable effective management of the site in the often fluid economic, political, and social contexts of the Wahgi Valley today.

A Personal Aside

I first met John in 1987 while an undergraduate in geography at Cambridge University. He was instrumental in my becoming interested in the geography and long-term history of the highland peoples of Papua New Guinea. Since then, he directly facilitated several aspects of my research in the interior of the country, including fieldwork in 1990 for a Master of Science in geography, during which time I stayed with his brother, Sali/Charley Muke, and other family members in the Middle Wahgi and Lower Jimi Valleys.

His continued community engagement with the Kawelka community at Kuk Swamp, as well as with Professor Jack Golson in Canberra, kept the metaphorical "road" open for me to undertake archaeological excavations there in 1998 and 1999 for my Ph.D. More recently, he has facilitated and supported – and we have worked together on – several archaeological research projects and cultural resource management projects in different parts of the interior of Papua New Guinea. The most significant of these is the inscription of the Kuk Early Agricultural Site to the World Heritage List in 2008. As I write this biography in 2012, we are still working together on Kuk and other projects in the country.

My indebtedness to John is clear from the above personal history. However, he has been a mentor to many others within and outside Papua New Guinea. Over the last 20 years, he has worked tirelessly, and often struggled, as an advocate of archaeological and cultural issues within Papua New Guinea. The cultural heritage of Papua New Guinea would be greatly impoverished without his efforts.

Multicultural Archaeology

Cristóbal Gnecco
Department of Anthropology, Universidad del Cauca, Popayán, Cauca, Colombia

Introduction and Definition

Archaeological discourses related to the creation and functioning of national societies have lost momentum and significance as a result of the emergence of multiculturalism. Multiculturalism has the main tenets of modern societies crumbling, especially the construction of unified collectivities (national societies) in terms of culture, language, and history. In the last two or three decades, multiculturalism has set in motion profound changes, especially regarding the organization of society, which is now premised upon the coexistence of diverse constituencies, conventionally referred to as *cultural diversity*. The modern struggle, often violent, to unify society has been abandoned. Indeed, multiculturalism does not demand "Otherness" (alterity) to be like the self; rather, it encourages Otherness to conserve (or to strengthen or to create) its diversity.

Archaeology has been shaped by this social order and a *multicultural archaeology* has emerged. In order to keep pace with multicultural changes (which archaeology has neither championed nor promoted but which it must accommodate, often unwillingly), profound as they are, four changes have taken place in archaeology: (a) its practice has been opened to local actors; (b) the circulation of discourse has been widened; (c) other historical horizons have been included in interpretations; and, (d) exclusive control of some disputed issues has been given up.

Multiculturalism is not an innocent realignment of society. It has been widely criticized by those who believe that it promotes cultural diversity but ignores the needs and expectations of those who are different. Cultural diversity is channeled to suit multicultural needs, mostly in a political vacuum. The multicultural celebration of diversity, which encourages the proliferation of local and specific identities, effectively weakens more inclusive, binding, and stronger identities. In a world of fragmented identities, no matter how strong they are individually, the system reigns. Multicultural archaeology also falls prey to such critiques. Further, while it tolerates different representations of the past and even the widening of their scenic display, it remains untouched in metaphysical and ontological terms. The masterstroke of archaeology in multicultural times – changing in order to remain the same – mimics what the textualist anthropologists of the 1980s did, about whom Johannes Fabian (1990: 761) wrote, "Should we therefore fear that what looks like a crisis is just a lot of noise made by anthropologists regrouping in their attempts to save their representer's privileges?" Archaeologists, members of

a privileged cognitive minority, do not want to lose the privileges granted to them by virtue of their ownership of a manner of representation that, at most, they are willing to share but are unlikely to change. Moreover, the acceptance of archaeology by dissenting agendas – the best known being feminist and indigenous archaeologies – is premised upon the idea that what has been wrong is not the discipline itself but the way it has been used. This has had the effect of strengthening and thus hardening its philosophical fabric. Yet, there are truly contesting actors that strip archaeology bare, exposing the functioning of the discipline in multicultural times and showing how it contributes to the reproduction of asymmetrical positions with regard to historical representations.

Historical Background

Archaeology related to nation-states through the creation of the national self. Archaeology provided the historical depth and the unified symbolism upon which modern society was formed. It provided the nation with the continuity it needed to not appear as a blatant transgression of what it replaced. The *new* (modernity, the nation-state, the national society) found in the *archaeological* (material-based discourses about antiquities and forebears) a deep density. What does it mean to be national/modern in archaeological terms? It means to update storytelling, to make it transcendent (objective, neutral), to bring a collectivity (national society) and a singularity (the modern individual) to recognize themselves mutually as whole and part, uniting them in a ceremonial, mnemonic space.

Archaeological time performed three functions: it was a measure of progress (society knew where it was, where it was heading, and where it came from); it was a means of control (individuals had to adjust to a temporal behavior that established an origin, a route, and a destiny); and it was the signal of a symbolic exchange (between society and expert knowledge). Archaeology was thus created by modernity to produce a new temporality, suited for the emergence of a national *us* (deep, homogenous, projective, and shared). From such an *us*, as in many other fields of the new nation (e.g., education, health, and law), Otherness was evicted. The archetypical *savage* (the negative counterpoint of the modern *us*) was cast as an outsider of modernity, its dark side, which was to be incorporated or eliminated.

For more than two centuries, archaeology and nationalism grew alongside each other. About two decades ago, the symbolic field of modernity was reorganized, especially with regard to the composition of society; a homogeneous society gave way to a heterogeneous one. As a result of this reorganization, the *savage* was no longer castigated but was elevated to a building block of the new society thus created: diverse, multiple, and plural. Multiculturalism assumed that the savage as *diversity* would abandon its role as a nemesis of modernity only to be tamed and organized. The political eroticism of modernity, whereby Otherness was attracted into the national society, was replaced by the tolerant coexistence of the diverse. The promotion of cultural diversity, unthinkable during modern times, is today a categorical imperative, in the plain Kantian sense, an autonomous and self-sufficient mandate.

The key words linking multicultural reforms are *recognition, autonomy*, and *limits*, especially with respect to ethnic groups. *Recognition* has been heralded, since the early 1980s, as the most important imprint of the new society. Indeed, as Charles Taylor (1994: 38) pointed out, there was a drastic shift from the politics of equal dignity to the politics of recognition:

> With the politics of equal dignity, what is established is meant to be universally the same, an identical basket of rights and immunities; with the politics of difference, what we are asked to recognize is the unique identity of this individual or group, their distinctness from everyone else. The idea is that it is precisely this distinctness that has been ignored, glossed over, assimilated to a dominant or majority identity.

Such recognition was not a mere statement, though, as Taylor continued, "But the further demand we are looking at here is that we all *recognize* the equal value of different cultures; that we not only let them survive, but acknowledge their *worth*" (Taylor 1994: 64; italics in the

original). However, what has become clear after almost three decades of multicultural policies world round is that Taylor's caveat was all but ignored. The multicultural conviviality of cultural diversity has not meant the recognition of the worth of the different but merely its existence, which has thus been organized and, to a large extent, isolated.

Varying in intensity and scope, multicultural reforms tended to secure or to consecrate the territorial, legal, educational, administrative, fiscal, and linguistic *autonomy* of culturally diverse groups. Provided that autonomies of any kind within national borders were always the conundrum of modern political theory, multiculturalism made certain that the autonomy it predicated was not meant to be the demise of the (relatively) cohesive societies that modernity strove so hard to build. As a result, autonomy was consecrated, but within *limits*. Taylor (1994: 62) stated, "liberalism can't and shouldn't claim complete cultural neutrality. Liberalism is also a fighting creed. The hospitable variant I espouse, as well as the most rigid forms, has to draw the line." Legal autonomy, for instance, is granted to minorities with differential conceptions and practices of justice, at times quite apart from modern law; yet, such an autonomy can only be enacted within cultural and territorial limits, that is, it can only apply to certain individuals and in certain places.

Recognition, autonomy, and limits all work together, in a tense yet productive entanglement, to build new post-national societies. However, one prominent symbolic field was apparently spared from multicultural reorganization: history. Multicultural concessions establish a limit set forth by state policies. There are borders that autonomy (ethnic or otherwise) cannot cross: a claim to national autonomy within the nation is one; history is another. History is still an arena – controlled by the state and by academic disciplines – for the deployment of a collective *us*, which becomes an increasingly blurred category in multicultural times. If modern archaeology once had a clear relationship with nationalism, now its home is in utter disarray. If before it administered discourses for dealing with an Other external to modernity, it now ignores what kind of discourses it administers given that such an Other is no longer an exteriority but a constitutive interiority. Is it to keep telling the history of a homogeneous, static, and disciplined *us*, even when constitutive Otherness strives to build itself in difference and disjunction and the cultural diversity multiculturalism widely espouses thrives? Or, rather, is it to write a new (multiple, plural) history in which those Others formerly banished are also represented, those very Others currently struggling to find a place and a time, no matter that they do it by claiming agendas that are utterly anachronistic for the West? In either case, the situation is a complex one for archaeology. If it embraces the former, it would be asserting that multiculturalism may have arrived, but nothing has really changed for the discipline. Yet, that assertion would be backed by the state itself, incoherently exhibiting its modern mnemonic apparatus intact, a strategy that would be utterly anachronistic were it not overtly calculated. (Central museums, for instance, are still national.) The state continues to endow its material referents and build its narratives with a particular yet universalized meaning; it simultaneously creates and condemns an inclusive identity. Legal jurisdictions establish the political legality of the state in the enactment of laws about heritage, which, in the end, regulate the enunciation of historical narratives. The latter endow expert knowledge (such as that of museums and archaeologists) with the right to establish and legitimate the apparatus of censorship that regulates the production and reproduction of historical discourses based on objects.

If archaeology champions the latter, that is, a multiple and plural history, whatever that may be, it would be sailing uncharted waters. That would not be a problem in and of itself if it were not for the unknown and unwanted surprises that may be waiting. For one thing, multiplicity would mean two things: either different histories living side by side – which is a naïve utopia, anyway, given the operation of hegemony – or an umbrella history, somehow modeled in national discourses, under which several particularities would bloom. For the other, a radical Otherness may wish to explode whatever there is left of national histories. In such

a case, reconstituting the shattered whole would be a tremendous task and most likely useless.

In archaeology a middle way has been adopted that feels safe and controllable; there is neither the reproduction of a national, unified history nor an unknown (and perhaps impossible) multiple history. The curious approach that has been adopted mixes a bit of old positivism, albeit nuanced, with another bit of a new constructivism. It is stated that the past is fully knowable through scientific means yet that the past is a historically shaped construction is also accepted. The latter, incidentally, entails the legitimacy of different accounts of the past. In its own way, multicultural archaeology follows a contemporary demand for social justice, which has become a necessity and, additionally, a trope (empty, at that). It engages diversity only marginally, almost unwillingly. Archaeology is not that engaged, after all, at least not in relation to the needs and expectations of nonacademic actors. Multicultural archaeology thus follows the threadbare and orthodox trails of positivism, it disdainfully observes (but selectively uses) the different histories that postmodern capitalism forces it to tolerate, and pleases itself by existing (with the security it obtains from the institutional apparatus) in a world of separate histories, tamed and exploited by the market.

This conundrum – the mix of *positivism* and *constructivism* – is not new. It has occurred in history a number of times. It was perhaps inaugurated by the Marxist insistence on the historical character of the superstructure and, at the same time, on the universality of historical materialism. Critical theory tried to find a way out this *cul-de-sac* by postulating the relativity of superstructural truths, checked by critical reflexivity and by their nesting in political realities. Some archaeologists have tried to bring this home. Moshenska (2009: 47), for example, has stated that "public archaeology in the broadest sense is that part of the discipline concerned with studying and critiquing the processes of production and consumption of archaeological commodities." But for most of archaeology this conundrum is nothing more than an unlikely (but powerful) normal cocktail, which defines the borders of *multicultural archaeology*, a strategy of disciplinary practice that, from afar (not the neutral distance of scientific times but the cynical remoteness of the political correct), contemptuously allows the existence of other historical accounts while it hardens its own operations. Thus, archaeology has accommodated to multicultural mandates by adopting a more democratic, tolerating outlook. In the meantime, other histories (whether based on archaeological narratives or not) strive to find their way. The net result is that historical fragmentation lives alongside a hardened, academic, and state-founded discipline, which by sheer ideology and hegemony still reigns, a pure multicultural product.

The multicultural hardening of archaeology *qua* Western discipline has been enhanced by so-called alternative archaeologies, which challenge the hegemony that have been enjoyed by positivist archaeology for so long a time. Indigenous archaeologies (Watkins 2000; Smith and Wobst 2005), for instance, depart from certain archaeological practices, especially if colonial, and may even position their own agendas, but accept the foundational principles of the discipline. Indigenous peoples even willingly offer to dissolve radical dichotomies: "Indigenous Archaeology is perhaps uniquely positioned to creatively challenge hegemonic categories and dismantle binary frameworks such as 'Indian' and 'archaeologist' " (Colwell-Chanthaphonh et al. 2010: 231). Good intentions notwithstanding, banishing a perhaps important confrontational dichotomy mostly serves to unite and solidify archaeology by making it more democratic. If the dichotomy indigenes-archaeologists was heated and strenuous some while ago, exclusive and irreconcilable, indigenous archaeologies would dissolve it. Theoretical work following Joe Watkins' (2000) book, which "has begun to explicitly frame Indigenous Archaeology as an effort to challenge the discipline's colonialist underpinnings" (Colwell-Chanthaphonh et al. 2010: 228), is based in the implicit that a "decolonized" archaeology can retain the modern core of the discipline. How can alternative archaeologies be defined "as multiple discourses and practices on things from another time" (Hamilakis 2011: 408) if they retain the ontological core of the modern

conception of time pasts? Can such "another time" be effectively enacted through/from modern ontology? Hardly so, because one of the main tenets of indigenous archaeologies, as put forward by one of its better-known proponents, states that "While focus and specifics may vary, one common thread among Indigenous archaeologies that I have observed is an incorporation of, and respect for, the experiences and epistemologies of Indigenous groups globally" (Atalay 2008: 29). For that reason, indigenous archaeologies are at odds to secure being an alternative to something. If *indigenous* is to retain an anti-modern stance (or, at least, a will to be alternative to modernity), where lay most of its political power and utopian promises, it cannot be an adjective to archaeology (a modern discipline practiced by indigenes) but a substantive implying alternative cosmologies in their own. In short, alternative archaeologies that retain the basic tenets of archaeology reassure Western cosmology. Further, alternative archaeologies are the best things that have happened to archaeology since the scientific consensus of the 1960s broke off: the Other is no longer a nemesis but an ally.

This rapid sketch of multicultural archaeology would not be complete without a discussion of the market. Going public, the motto of multicultural archaeology, is tantamount to going into the market while preserving a democratic, open, and tolerant attitude. But it may be the case that the way archaeology has so eagerly embraced the market in the last three decades – in Cultural Resource Management/Cultural Heritage Management (CRM/CHM) operations, museums, the heritage business, and revival parks – is a symptom of its uneasiness. Instead of facing head-on the riddles created by opening up the formerly closed field of historical representation, archaeology goes placidly to the marketplace and delays the confrontation of other realities, hoping that such a deferral will last forever.

Key Issues/Current Debates

The characteristics that define a multicultural archaeology can also help to outline the most pressing issues it now faces. They can be better grasped, however, by first presenting the general critiques raised against multiculturalism itself.

A Critique of Multiculturalism

The coexistence of diverse cultures is a trademark of multiculturalism; yet it is a politics of diversity based on the *recognition* of a stereotypical, virtual, and segregated Other. The "real other" (who responds diversely, not always pacifically, democratically, or humanistically to the pressures of savage capitalism, to the speed of global fluxes, and to postideological violence) must give way, without stridencies, to an "imagined" Otherness (who lives its bucolic and exotic life in a world of tolerance and separation, assiduously visited by the market). As Slavoj Žižek (1998: 157) noted, multicultural tolerance

> excuses the folkloric Other, deprived of its substance (as the multiplicity of 'ethnic foods' in a contemporary megalopolis show) but denounces any "real" Other due to its 'fundamentalism,' given that the core of otherness exists in the regulation of its pleasure: the 'real Other' is, by definition, 'patriarchal,' 'violent,' never the Other of ethereal wit and charming customs. One is here tempted to re-actualize the old Marcusean notion of 'repressive tolerance,' considering it now as the tolerance of the Other in its aseptic and benign form, which forbids the dimension of the Real of the pleasure of the Other.

Terrible concepts, indeed: regulation of the pleasure of Otherness; repressive tolerance; stigmatization, and, at the same time, promotion of primordialism. Multiculturalism organizes cultural diversity, nominating and creating it from the state, multilateral agencies, nongovernmental organizations (NGOs), and the academy, while the "real" Otherness is repressed by its virtual reflection. It neutralizes the activism of the different by imposing limits, legal and otherwise, and by delivering it to the market, which treats it just as diversity, controlled and promoted as authentic and pure.

The distance between diversity and difference is thus the main multicultural limitation, both a characteristic and a symptom. In fact, the decades that followed the last world war, but especially the last three decades, have witnessed the general

abandonment of pejorative and stigmatizing categories (inferior, primitive, and underdeveloped races) and the enlivening of cultural relativism (diverse cultures) that deactivates wide-base organizations, deracializes racism (but keeps it intact), and reifies/functionalizes differences (as diversity) to downplay inequalities. As Claudia Briones (2005: 22) pointed out, "Cultural difference emerges as a quasi-ontological property because social relations that recreate processes of alterization are presented and explained unlinked from the organization of capital and from international and national power." The multicultural idea of diversity wants heterogeneity to be understood as "a mosaic of monochrome identities" (Brubaker and Cooper 2000: 33), eliminating historical specificities, processes of alterization, asymmetries, and power relations. Therefore, it is necessary to establish the distance between diversity – that which multiculturalism promotes: quiet, safe, exotic, complacent, organized, and mercantile – and difference – the "constant production and emergence of subjects in the onslaught of their antagonisms and tensions" (Segato 2007: 27–28) – and to understand Otherness in its happening.

As if this were not an almost insurmountable problem, multiculturalism is fraught with constitutive tensions, the most prominent of which are the contradiction between individual and collective rights, and the autonomy accorded to different symbolizations of society and life. Although the latter has been curtailed by the establishment of limits, it nevertheless remains potentially explosive. The "solution" multicultural societies have adopted to solve these problems is deferral and, when circumstances are pressing, casuistry.

A Critique of Multicultural Archaeology

In light of the critique of multiculturalism I have just sketched, I can also posit a critique of multicultural archaeology with regard to its main characteristics: (a) an open practice; (b) a widened circulation of archaeological discourses; (c) an expanded archaeological hermeneutics; and (d) an abandonment of its control over certain issues. Firstly, the *open practice* it champions has only allowed local actors to be members of research teams or, at most, to be trained in the discipline. Such openness has normally been framed under the heading "collaboration," but power relations are rarely at stake. Most archaeologists are content to offer cultural crumbs to communities (a local museum, a video, a booklet) while preserving the control of key issues (research designs, destination of findings, production and dissemination of narratives). Secondly, a *widened circulation of archaeological discourses* – which, along with collaboration form the backbone of so-called *public archaeology*, part and parcel of a more comprehensive entity that I have chosen to call *multicultural archaeology* – has had two results: it reproduces the archaeological canon more widely, and it furthers the reification and objectification of the past, such as in the case of local museums. Thirdly, *an expanded archaeological hermeneutics*, achieved by incorporating non-Western conceptions of the past, has doubtlessly enriched the explanatory potential of the discipline but has not engaged intercultural understandings. Such an interpretative expansion, many times resorting to alien cosmologies that produce curious argumentative hybrids (for instance, live objects, with agency, amidst rigid functional frames), deepens a logocentric arrogance but does not aim to forge non-hierarchical relationships. As a result, historical diversity (that is, differential interpretations of the past, including the conception of what the past is) is a mere instrument for a more vigorous archaeology. And fourthly, *relinquishing control* over certain issues means precisely that: *certain* issues and under *certain* circumstances. This characteristic has been more commonly achieved through the selective repatriation of biological and cultural remains. Although repatriation is an important resource whose potential for social movements cannot be doubted, it is worth asking why it has become so central and visible for archaeology. As if answering such a question, Chris Gosden (2001: 258) noted, "The agency of native peoples in the past in creating colonial forms has a strong echo in the present, where demands for archaeologists to create more locally sensitive views of history are now backed by legislation. This means that present research must be a collaborative project

between archaeologists and local people and that this can only come about *once the injustices of the past have been redressed, which will often mean the return of skeletal or cultural material* considered to have been inappropriately obtained, stored, or displayed" (italics added). Repatriation is a highly debated topic in contemporary archaeology, not so much because giving back sites, things, and remains undermines the fundamentalist view of most archaeologists, but because it has become the ideal place to expiate colonial guilt. Archaeologists are firmly convinced that repatriation will heal *the injustices of the past*. Their sacrifice is rather small: returning (or sharing) a few things while preserving their cognitive privileges, the logocentric gaze, a solid narrative network, and their mnemonic impact.

In short, multicultural archaeology participates in the incoherent multicultural historical discourse, whose *us* has never been so blurred. Besides, it intentionally postpones the solution of the tensions it has contributed to creating, such as the purported autonomy of historical representations. It does so by treating different conceptions of history as a mere isolated diversity – suitable for market exploitation, as in the heritage boom of the last three decades (Martín 2000) – with no consequences whatsoever for society at large.

Future Directions

Current times – postmodern, transmodern, postindustrial – show the new face of bourgeois society, in which identities formerly antagonistic and exclusive now coexist amidst the placid (yet, proven explosive) pacifism of multicultural relaxation. A wide variety of genders and ethnic groups are now a part of the current landscape of the world, whereas before there were only heterosexual and national citizens. Such an unlikely coexistence is the crowning achievement of contemporary capitalism – even more so than replacing commodities by desire in the imagination of people.

Until two decades ago, non-Western histories and their way of relating to materiality and heritage were unknown to the state and to academic disciplines. The symbolic field of history was rather stable and unified around the national self. What has made those histories visible now? Anti-colonialists struggles, of course, but also a more subtle reason: the multicultural search of diversity, the appropriation and neutralization of the different that, in other circumstances, could destabilize the already stabilized by dint of hegemony and hard ideological work. (In this new hegemonic act, fully agreed to by the different, the market thrives.) In this apparently open and horizontal scenario, a "reformed" archaeological establishment is happy to concede to former marginal actors what it cherishes most: epistemic disciplinary coherence. Its gains are numerous. It keeps practicing archaeology as it has been known (it changes nothing of its metaphysical and ontological fabric); it does it publicly (generously); it feels more democratic (by *sharing*); it gets closer to what used to be called *the savage*, appeasing his/her desires and convincing itself that disciplinary nearness translates into spatial, temporal, and cultural coalescence.

But dissonance and confrontation have not ceased to exist; they can be gauged by examining the relationship of archaeology with indigenous peoples, still its most ferocious opponent. To begin with, indigenous peoples and archaeologists think, feel, and expect different things of their mutual concurrence to the discipline. For the archaeologists, the issue is crystal clear: the indigenous acceptance of an open and democratic (multivocal) archaeology is the best hope for their future. Multicultural archaeologists are delighted to share their knowledge with the masses, dressed with ethnic garments. Their enlightened move pleases them because they disguise as altruism and political correctness their unwavering commitment to the Western cosmology. On the other hand, the positioning of indigenous peoples before archaeology is not consensual. Some value archaeological processes and results if they are part of their agendas, considering that material objects and features turned archaeological by academic or community-appropriated discourses can serve to strengthen historical reflection, central in social mobilization and life. Others confront

archaeology and reject altogether any possible transaction with it. A perusal of the geographical distribution of those two antithetical positions will show that the former is mostly exercised by native groups in industrialized democracies while the latter characterizes most indigenous peoples in the old Third World. Such a distribution is not odd; it closely responds to the differential effectiveness of multicultural policies, to how successful they have been in building strong hegemonies, accomplished more completely in those countries where nationalism was more aggressive and triumphant.

Those who confront archaeology and want to know nothing about it raise their voices from a discursive emergence, from a distance, even from an assumed exteriority. They expose and challenge what the West has done and drag its institutions, including academia, into the fight. Confrontation of the West is not new – it is centuries old – but it gained more coherence and strength since the 1950s, starting with the anticolonial wars in Africa. It has increased its pace and intensity in the multicultural stage, where actors with opposed agendas concur. One of the actors concurring to the historical scene reconfigured by multicultural policies, of which repatriation is one of the most prominent, is archaeology. By its mere concurrence it pretends to forget that something is happening, that some people challenge its work. Archaeologists then sink in utter silence and keep on doing what they have always done, protected by a solid and conservative *esprit de corps* nurtured by esoteric meetings and publications, or they talk the multicultural language. They talk about dialogue and participation. They talk an empty language. But, should archaeologists be surprised that their work is now contested, many times from an aggressive radicalism that they see as unjustified violence against their hygienic operation? The perhaps good intentions of archaeologists, convinced that their sharing of archaeological secrets is the ultimate concession democracy can dispense, bounces back against a solid wall of rejection at the grass-roots level.

Multicultural archaeology opens the world of representation and gives access to other subjects who represent; however, it wants representation to be a mere nonpolitical epiphenomenon of the hierarchical relations it seeks to preserve. The multiple representations of the past that are incidentally released by the autonomy inherent in multicultural reforms (although historical autonomy is conspicuously absent from constitutional and legal mandates) are separated from the world of power. But, what happens if we consider representation as praxis, as suggested by Johannes Fabian (1990)? It would happen that the presence of the Other is felt, lived, and accepted outside of representation as a epiphenomenon – a representation that, at any rate, has been premised upon the absence of the Other. If a plural, horizontal, and open world (historical and otherwise) is to mean something beyond harmless relativistic pluralism, it can be found in the struggle for a radical Otherness. Rita Laura Segato (2007: 18) wrote in this regard,

> The fight of those social movements inspired by the project of a 'politics of identity' will not achieve the radical nature of the pluralism it intends to assert unless insurgent groups depart from a clear conscious of the depth of their "difference," that is, the proposal of an alternative world that guides their insurgency. I hereby understand such a difference not as with regards to substantive contents in terms of supposedly traditional, crystallized, still and impassive 'customs' but as difference on goal and perspective by a community or a people.

The radicalization of Otherness means the liberation of its force, restrained by the nets of cultural diversity. It is to think it as happening (to think relations, becoming, powers), something that can destabilize the stabilized. To destabilize the archaeological canon: that can be the minimal purpose of an emergent tradition that disbelieves, deviates, from multicultural archaeology. As Arturo Escobar (1996: 39) wrote about his book against development "the purpose of the analysis is contributing to liberate the discursive filed so the task of imagining alternatives can begin." Because we dwell in naturalized worlds – created by the cultural, social, political, and economic hegemony of a system, a class, a cosmology – trying to dwell in denaturalized worlds is not easy but surely not impossible. We first have to make them, or to unmake them, liberating the

discursive field. That (un)making is a task of happening: something that is, becomes, lives.

Multiple Microfossil Extraction in Environmental Archaeology

M. Alejandra Korstanje
Instituto de Arqueología y Museo-FCNeIML, Universidad Nacional de Tucumán Instituto Superior de Estudios Sociales – CONICET/UNT, Tucumán, Argentina

Introduction

Microfossils can be defined as biogenic particles invisible to the naked eye and deposited in any type of soil or sediment context (Coil et al. 2003: 991). These may typically include ancient silica phytoliths, diatoms, faunal spherulites, starch granules, calcium oxalates, cellulose rings, chrysophytes, and micro-charcoal, but any other microscopic particle that is an organism itself or that is part of one may also be included in the definition. This type of research recognizes its origins in phytolith studies (since Pearsall 1978; Piperno 1988, and many others), but it gives other microfossils the same level of importance, partly based upon the development of low-chemical extraction procedures that allow more types be preserved. Laboratory procedures optimized for obtaining as many types of microfossils as possible in a single extraction process have been explored (Coil et al. 2003; Korstanje 2003, 2004), leading to what today may be called "multiple microfossil analysis" (Korstanje 2009). The idea of obtaining multiple microfossil assemblages from the same extraction process has the benefit of allowing a high number of samples to be run without the specific procedures required for each type of microfossil. This approach also circumvents some of the more complex taxonomic analysis and interpretations, which require qualified experts for each of kind of microfossil. However, to answer some research questions, this kind of sophistication is not necessary, and processing for individual types would require many extra working hours using processes already known to be time-consuming. Conversely, for human

perception skills, the possibility of having multiple microfossil types together on the same slide gives the researcher an instant idea about the microfossil assemblages and patterns that might differentiate, for instance, a corral structure from an agricultural enclosure. Finally, the protocols used for multiple extractions do not always require sophisticated laboratory conditions, and their use has led to interesting results regarding the recovery of microfossil assemblages.

Since this methodology started to be used, many scholars in South America and other parts of the world have been improving it, especially for the study of agricultural soils, cattle management, environmental issues, food production and processing, and artifact use in archaeology.

Definition

Laboratory Procedures

The multiple microfossil extraction procedure consists essentially of a low-chemical protocol, which follows several of the ordinary steps for phytolith extraction, with minor modifications. An added benefit of developing low-chemical and low-tech extraction protocols is the lower hazards and costs associated with such approaches.

Samples are dried in the laboratory oven at low temperatures until weight is stabilized. Equal splits of soil samples are deflocculated by adding sodium hexametaphosphate overnight. Clays are separated and eliminated by gravity using only distilled H_2O in the liquid columns. Decantation times are determined according to Stokes' Law, using a centrifuge. Samples are then sieved (50–55 mm mesh) for removal of sand (which is separated but stored to scan for larger phytolith types), and then silts are separated. Then silts are floated using the centrifuge in a zinc iodide (ZnI_2) heavy liquid solution, prepared at a density of 2.3. There are references in the literature to the use of sodium polytungstate as the heavy liquid for floatation, but this chemical can have unfavorable results in some soil conditions, and since this was the case here, zinc iodide is a recyclable salt that was used instead and found to work well.

After establishing the possibility of using faunal spherulites as evidence for the deposition of camelid dung, experiments were conducted with modern dung samples from the species *Lama pacos* and *Lama glama*, in order to determine the susceptibility of these microfossils to destruction by some common extraction chemicals. To determine whether these procedures were equally valid for most of the microfossils being looked for, tests were run which included different combinations of solution densities, mounting media, time, and temperature conditions for drying (Korstanje 2003, 2004). These experiments clearly showed that when used as the heavy liquid for microfossil extraction, ZnI_2 does not damage or destroy any of the non-silica microfossils, e.g., starch, pollen, or spherulites.

Finally, we tested whether our protocol was adequate for producing visually clear slides for microfossil identification purposes or whether protocols with higher chemical impacts would allow more specimens to be identifiable. Again, projecting the numbers obtained to equivalent density measurements, the comparison shows that the protocol used is appropriate to allow even the most specific types of silica phytolith identification (Korstanje 2009).

Historical Background

Over the last 40 years, phytolith researchers have developed the tools to directly approach landscapes, open-air sites, and artifacts, in contexts where macro-remains are not preserved. In the 1980s, one of the field's principal specialized manuals indicated some of the roles of phytoliths for archaeobotanical studies (Piperno 1988: 168) as:

1. The origins and dispersals of domesticated plants and development of agricultural systems
2. The availability, economic usage, and noneconomic roles of wild plants
3. The nature of environments and environmental modification associated with past human occupation of sites
4. The relationship between technology, economy, and social organization.

Most archaeologists interested in economics and food production were excited enough with these types of possibilities, but there were still more topics which could also be added to the approach from this point of view, such as site formation processes and taphonomy. Following this logic, we started our research on agricultural systems in El Bolsón valley (Catamarca, Argentina), but once we realized the limitations of phytolith analysis for our area, much of the enthusiasm passed away and showed us that we needed extra tools to answer our questions. Since then, we have refocused the research on the possibilities of whole microfossil assemblages as a tool for studying ancient agricultural sites (Korstanje 2009).

The study of Andean pre-Hispanic agricultural technology in the high semiarid valleys of northwestern Argentina has required multiple archaeological dimensions to be integrated into the research:

(a) The range of Andean crop spheres may include both high-altitude taxa (tubers/pseudo-cereals) and middle-altitude taxa (maize, beans, chili pepper, squashes).
(b) The possible occurrence of a relationship between husbandry and agricultural practices (fodder, fertilizers, alternating the use of corrals as agricultural fields).
(c) The coexistence of irrigated and nonirrigated systems.

In northwestern Argentina, phytolith analysis was initially inspired by the low levels of macrobotanical recovery from open-air fields, found at high-altitude, semiarid sites occupied during the early phases of agriculture. Phytoliths were the main target microfossils at first, because they were the most durable type of plant microfossil and there was also an existing tradition in these studies in South America (Zucol et al. 2008). As processing of phytolith reference materials and archaeological sediment samples progressed, the limitations of a phytolith-centered approach became more apparent. For example, few of the indigenous tuber taxa and *cheno-am* taxa potentially cultivated during the early phases of these occupations produce diagnostic or abundant phytoliths. At that point, the only regional crops seemingly amenable to producing phytolith evidence were maize, beans, and cucurbits (Piperno 1988; Korstanje and Babot 2007), certainly important crops but not sufficient for explaining ancient Andean agriculture.

Apart from the limitations relating to the set of plants growing in the area and the possibilities for their representation through phytolith production, the identification of plant taxa from the fields was crucial for demonstrating what people directly cultivated as opposed to what they consumed or exchanged, since most investigations of agricultural research questions are derived from samples from domestic contexts (Pearsall 1978, 1993; Rosen and Weiner 1994) or from lagoon systems (Kealhofer and Piperno 1994). This difference in the origin of the samples is important, since agricultural sites are open-air sites which do not have the stability of lagoons, as their soils have been plowed and worked at various times. Eventually, extraction and examination of additional microfossil types have not only enhanced the interpretive potential of the phytolith data in this research but have also produced data sets that have been more relevant to the given research questions. For instance, multiple microfossil types support interpretations related to site formation as well as to soil use and function.

To arrive to what today is called multiple analysis methodology, the spirit of earlier phytolith research that considered only two types of micro-remains together (e.g., Kealhofer and Piperno 1994; Campos et al. 2001) was followed to some extent. In those cases, the major advantage was to enhance the potential of one microfossil over the other, for example, using pollen for Asteraceae (difficult to identify from phytoliths) and phytoliths for Poaceae (difficult to identify from pollen) or other possible combinations within siliceous algae and phytoliths. Although they were still the result of different laboratory procedures and research methodologies, studies like these were the first alert that showed that two microfossils together explained more than one alone while strengthening the individual possibilities.

Good environmental and soil conditions for microfossil preservation encouraged further use of starch grains, within a wide variety of non-silica microfossils. From the first stages of the research, it was readily apparent that sediment samples contained at least some well-preserved starch. Starch granules in these areas have turned to be especially important, due to the variety and importance of tuber crops in the Andes, which have found to produce no clearly identifiable silica phytoliths or to produce none at all. Much effort was therefore put into exploring how different types of multiple microfossil protocols might affect starch recovery and damage (Korstanje 2003), to preserve the ability to make taxonomic identifications and reliable calculations.

After development of this laboratory goal perspective, the next step was to go straight into microfossil research with an extraction protocol and including the analysis of all possible microfossils (faunal, algae, and botanical) and their relationships with the characteristics of the soil matrix. This matrix is the natural and cultural context which can be used to make sense of microfossils. These assemblages explain some of the trends in a site's formation processes and, more importantly, are positive evidence of cultural practices in ancient soil use (Korstanje et al. 2014).

Key Issues

The Potential of the Microfossil Record in Relation to Agriculture and Domestic Activities

From the early years of this research and development of the methodology, it has been suitable to identify early husbandry practices from archaeological open-air fields and rock-shelter contexts and to track the chronological and spatial distributions of economic activities for a better understanding of ancient soil use and the archaeological components that survive to the present. However, specifically for agricultural research problems, a methodology considered to be a step further than "multiple microfossil research" is being improved upon by combining and jointly interpreting other soil science information (Korstanje and Cuenya 2008, 2010). The chemical characteristics of a soil under agricultural use covary depending on whether the crop plants contribute or extract various substances or elements. The parameters used to understand each field and soil use condition are principally organic matter and phosphorus, since although there are other chemical elements that can be added or removed during soil use (such as nitrogen, calcium, iron, etc.), it is these two components that are the most stable for studying ancient soils (Porta Casanellas et al. 1994). This is because, even if soils are not closed systems, nor encapsulated and isolated in time, some stable features such as P are preserved in time and become indicators of the prehistoric uses of soils.

Regarding corrals and pens used for domesticated animals, the multiple microfossil approach is important in two ways. At a micro-regional level, distinguishing corrals from agricultural fields can be an important issue, and this is possible if there are some well-preserved paleofeces with which to make a comparison and where phytolith patterns from dung (frequencies and types) should be clearly detectable in some of the soil samples. In such cases, the additional microfossil indicators of spherulites are useful for interpretation of structures as corrals. In another example, microfossil assemblages extracted from a well-preserved camelid dung layer in a rock-shelter site have suggested that domesticated camelids may have been fed with some of the same crops that humans consumed, since *Cucurbita* sp. and *Zea mays* phytoliths were found in the preserved dung. As was the case in Brochier et al. (1992), analyzing several types of microfossils together, especially examination of the relationship between phytoliths, diatoms, and faunal spherulites, could also improve interpretation of the depositional origins of these assemblages.

At a larger regional level, the composition of dung may help to understand the routes taken by nomadic pastoralists and caravans, because there might be more diversity in grasses and therefore in phytolith assemblages from dung (Korstanje 2004).

The methodology has also been suitable for revealing the complex functionality of structures where site uses had previously been assumed from architectural features alone – including residential areas, agricultural fields, corrals, or a combination of these (Korstanje and Cuenya 2008, 2010). To some extent, the methodology has also been applied to broader topics, such as understanding artifacts used for food processing and meal preparation (Babot 2009) or evidence for the consumption of hallucinogens in residues from pipes and other artifacts (Martin Silva et al. 2016). In these last cases, the laboratory procedures were adapted due to the small amounts of sediment and residues recovered, with almost no laboratory processing necessary in the extraction and following a similar low-chemical approach as with multiple microfossil extraction.

Microfossil Associations, Physical/Chemical Soil Characteristics, and Human Activities

After realizing the advantages and possibilities of incorporating multiple types of microfossils (Coil et al. 2003), it was necessary to evaluate their potential contributions as data for a specific research problem. Assuming that there would be poor organic preservation in open-air fields and sites, research strategies were designed to include the analysis of microfossil assemblages. In addition to its particular taxonomic identification, the relative frequency of each type of microfossil by locus and structure type is considered relevant for distinguishing practices and activities in agricultural landscapes and sites.

Phytoliths are good indicators for identifying grasses, but for a micro-region such as a valley, there may be not enough variability in grass species to characterize clear patterns. The cultivars recorded in the Andes are not equally as recognizable in the archaeological record. However, among them is maize, as a grass in the Poaceae family that is major producer of silica phytoliths in its vegetative as well as reproductive structures, and there can be a high expectation of finding diagnostic maize phytoliths in areas where maize has been cultivated. Alternatively, since potatoes are in the family Solanaceae, which does not produce diagnostic phytoliths, there is no expectation of finding them, but instead it is possible to anticipate diagnostic starch granules. In this way, taxonomic determinations are performed using broader microfossil assemblages, using silica phytoliths and starch granules for the determination of Andean crops (Korstanje and Babot 2007). From these examples, scholars interested in using this methodology should review the expectations appropriate for their own study area and plant record.

Calcium oxalate crystals from plants have very restricted diagnostic potential and, since they are quite fragile, are not recoverable in most contexts. However, since these always occur in modern samples of camelid feces, they can be used as supporting evidence for the presence of feces when faunal spherulites are also present. These have recently been shown to be very important working in specific small-scale contexts, such as pipe residues, where a narrow group of hallucinogenic or narcotic plants are expected to be present. Cellulose rings also have very limited diagnostic possibilities, but they are very common in fibrous taxa such as plants from the Bromeliaceae family, so these can be recorded as present/absent as possible indicators of plants used for traditional crafts.

In South America, siliceous microalgae, such as diatoms, are mainly used as an indicator of irrigation, based upon their frequency of appearance. Even though diatoms have taxonomic importance for specialists and may give information about their immediate environment in ancient times, in multiple microfossil analysis, they are taken only as an auxiliary evidence for those cases where a genus from a very specific type of environment is present in the samples. This is because at a micro-regional level, diatom assemblages do not necessarily present enough complexity to reflect subtle environmental conditions or changes. Instead, diatoms are more useful for explaining regional diversity in broad categories (dry/humid, salty/non-salty, marine/continental, etc.).

The Chrysophyceae are lesser-known (golden brown) algae, reported as nitrogen indicators (presence/absence). This level of identification is similar to that usually applied to microscopic

charcoal, which can be used to identify the presence of fires, although it is not used for taxonomic identification of the wood's origin.

Finally, since Andean camelidae spherulites can be differentiated from those of European cattle (Canti 1998), but cannot be used to distinguish different camelid species, these are used on a presence/absence basis to indicate dung or to indicate the arrival of European cattle. Nevertheless, spherulites must be taken into account with care. Their presence indicates dung, regardless of the abundance (while not necessary manure), but their absence does not indicate absence of dung, as it has been seen that the same animal in different environmental situations may produce large quantities of spherulites or none at all (Korstanje 2004). We have the additional problem that camelid herds in the past, the same as today, were fed with the remains of harvests, and therefore, their manure may contain the same phytolith assemblages as the agricultural fields. Likewise, during fallow times, the same grasses that camelids graze may easily propagate in the agricultural fields as these seeds can be carried in dung. Consequently, the phytolith assemblages may be similar in both cases. At this point, phytolith assemblages may be useful only in comparing the frequencies of different phytolith types and cross-checking with other independent archaeological evidence, such as architectural features or other characteristics of the locality if no architecture is present.

Once scholars have researched the regional circumstances, the local characteristics of each microfossil assemblage, and the preservational features based upon soils, sites, and climates, the next step is to put all these data in dialogue with the research questions. For instance, freshwater diatoms in a context with a high-frequency assemblage of middle-altitude crop phytoliths might be considered as an indicator of irrigation, while starch granules from pseudo-cereals and faunal spherulites in a context of low-frequency assemblage of middle-altitude crop phytoliths may indicate fertilization and/or nonirrigated agriculture, among other sets of possibilities.

Based on criteria similar to those described above, it has been possible to find a correspondence within every set of microfossil combinations and soil characteristics, matched with expectations from the perspective of ancient soil use. Some proposals can be presented for the research area in the following synthesized way: if there are α and β in x proportions, we can assume a κ use of land. For example, if we find high values of organic matter (O.M.) and an average abundance of silica phytoliths, we can infer that the soils have not been used for agriculture (Korstanje and Cuenya 2010). It is important to remember that these are comparative, not absolute, values, and so "high" does not mean any particular number but a value that is higher than that of the control sample. This interpretation should also be considered in relation to particular local, contextual, or environmental factors. To follow this reasoning, it is important to remember that even if microfossils represent independent evidence in the epistemological sense, they should be explained in relation to contextual data, including archaeological architecture and artifact analysis. We cannot consider them without taking into account the fact that, as with any other archaeological ecofact (e.g., macroscopic plant or faunal remains), similar combinations may lead us to infer different circumstances or activities depending upon the context of recovery.

It is also important to stress that, as this methodology can be used to study other agricultural systems besides those of the Andes, scholars must create their own baselines for research, as some of the initial conditions may be different.

Taphonomy, Regional Aspects, and Limitations of the Methodology

One of the main strengths of phytoliths as a type of archaeological evidence is that, under normal conditions, they are deposited in the soil directly in situ after the plant decays (Piperno 1988). However, it is important to consider the intromission of phytoliths from the soil fraction transported by wind in arid environments. In fact, this condition is quite important when studying open-air production sites, although is a matter of taphonomy and site formation process that can be evaluated just as in any other archaeological feature and situation. In some cases, for example, there may be an advantage because the sites are

located on high mountain slopes, where neither the water nor the wind can carry in sediments from other locations. However, in this case, we have the opposite effect: high levels of aeolian and hydraulic erosion lead to a high loss of the soil's silt fraction. In this sense, it is likely that a high proportion of the original microfossil assemblage has been deposited in the lower areas and lagoons of the valley.

Also, it has been assumed that phytoliths are highly stable in soils and show little mobility, constrained by the same taphonomic processes as any other particle included in the silt fraction. In soil science, it is considered that at a textural level, there is stability of the particles in the silt fraction (Porta Casanellas et al. 1994), but this does not mean that there are no micro-movements of the individual particles. In a soil under agricultural use, periodic plowing incorporates an extra dynamism to soil weathering and leaching. However, this does not create any definitive limit for the study of ancient soils, since this type of bias can be avoided by making comparisons among samples from similar types of environments and soils. In other words, soils from similar environments are easier to compare (e.g., arid to arid), but unless one carries out a comprehensive taphonomic analysis for each situation, comparing soil uses between two very different environments is not recommended (e.g., arid to humid).

Regarding microfossil specimens and classes, taphonomic and site formation factors may also cause differential preservation of siliceous and non-siliceous microfossils. While the first group will prove to be harder and more durable in general, silica phytoliths and diatoms may also be broken by physical action, altered in general shape, or become thinner and more translucent due to chemical processes of the natural silica cycle. Spherulites are very fragile not only to physical conditions but more importantly to chemical conditions. Also, the morphology of many starch granules has been shown to be affected by surrounding conditions. The reasons could be related to either natural site formation or diagenetic processes, but also to processes of cultural manipulation, or to laboratory extraction procedures. Natural and ancient cultural damage is not considered as a problem but as a source of information. These situations only affect the possibility of making a precise diagnosis of origin, but, as already noted, although taxonomic recognition may be desirable, it is not a critical issue for this kind of research, as it involves work at the level of microfossil assemblages in order to infer the general environmental or cultural patterns, rather than only to classify the taxonomic origin of individual specimens.

Future Directions

The developing trend toward multiple microfossil extraction and interpretation appears to represent a positive direction (Korstanje et al. 2014). Experiences with microfossil research in archaeology make it difficult to justify any programmatic statements regarding how microfossil research should be done. A better understanding of the nature and taphonomy of microfossils shows that in most cases a single microfossil type would not be sufficient to grasp the dimensions of the entire problem of ancient animal/agriculture relationships. Such a methodology may be perfectly applicable in other environments or parts of the world, but, of course, knowledge of all the factors and particularities related to the soils, plants, and people in these other areas must also be taken into account by the researchers.

A wider range of microfossil types can contribute to archaeological problem solving, and the further development of "reconnaissance" and low-destruction laboratory protocols are directions that will help microfossil research in archaeology to further advance and also to become more accessible to more archaeologists. Having the ability to view several microfossil types on a single slide aids interpretation of individual microfossil types while opening up new research questions and archaeological contexts.

The results of 20 years of research suggest that a wide range of microfossil assemblages may most effectively address research questions regarding agricultural and production systems. For example, when discussing economic crises in the ancient past, those have involved shortages

in staple foods or breakdowns in systems for their production, storage, or preservation (Pilaar Birch and Wallduck 2001). To test this, through collaborations by an interdisciplinary team of geologists, pedologists, palynologists, and archaeologists with various specializations, but particularly on microfossil research, it is possible to observe the existence of micro-changes at the environmental and landscape level. Also, when these lines of microfossil-based evidence are combined with information from more traditional archaeological avenues such as architectural interpretation of site function, spatial distribution of material evidence for economic activities, and geomorphological signs of field irrigation, the possible interpretive advantages of jointly extracting and interpreting several types of microfossils become apparent. An important point is that these data come from the field record itself rather than from inferences based on macro-remains in residential areas or on ethnographic records and analogies. Therefore, combined studies of soil and microfossil assemblages have demonstrated new possibilities in archaeology for recognizing and explaining activities directly from the sites.

Microfossil research in archaeology continues to develop on a truly international scale and, even when performed following the footprint of each region and its academic traditions, is to some extent open to the exchange of results and ideas. New advances and wisdom can be found well beyond the mainstream of Anglophone literature. Established and emerging research will also expand the range of research questions addressed with microfossils, especially using experimental archaeology to identify patterns of microfossil distribution and to associate these with the activities that produced them.

Multivocality and Archaeology

Carol McDavid
Community Archaeology Research Institute, Inc, Houston, TX, USA
Rice University, Houston, TX, USA

Introduction

This entry will attempt to define multivocality and describe how it has been used in archaeology, as well as explore some of the strategic issues and challenges inherent when attempting to enact it in practice. Part of this discussion will situate multivocality alongside other issues which usually accompany it or are sometimes conflated with it, in both theoretical and practice-based (case study) writing.

Definition

A textbook definition of the word is "many voices" – a fairly simple idea which becomes more complex in practice. The idea of "voices" can refer to differences in opinion, ethnicity, class, education, gender, culture, and just about any other form of human identity and variation that exists. In addition, people who claim one voice or another as "dominant" in one particular context can just as easily claim another in a different context – in some situations a person might speak as "a woman," in others as "an archaeologist," in others as "a Native American," in others a "business person,". . .and so on. A key point, when considering multivocality, is that each person has the potential to speak and identify with many different voices, even if they may choose one over another in any particular political or social situation.

Key Issues/Current Debates

In archaeology the idea of multivocality most often refers to the either the differences between

M

professional archaeologists (so-called experts) and the diverse publics that archaeologists deal with or the differences between the different publics themselves. In addition, it refers to the ways that these different people and groups value, interpret, and find meaning in any given archaeological site, as well as the narratives they create about places and objects. These differences do not necessarily fall into predictable, seemingly simple categories of ethnicity, training, gender, and the like. In addition, although the realities of "standpoint" and individual perspective are critical when considering multivocality, how it plays out in practice varies from situation to situation, project to project, and person to person.

Multivocality is one of several ideas that are central to the practice of postprocessual archaeology, although it has found expression in other forms of social inquiry as well – postprocessual archaeology does not "own" multivocality, even within archaeology, even though much can be found about it in postprocessual writing. Some other postprocessual ideas, which are related to multivocality and often discussed at the same time, include reflexivity, interactivity, relevance, criticality, openness, transparency, and pluralism. In projects which aim for multivocality, both archaeologists and diverse publics (or, to use a currently popular term, stakeholders) attempt to find ways for different points of view about history, meaning, and physical remains to be expressed, *at the same time*. The ideal scenario is that they do this *together*, that power (to "own," control, interpret, assign meaning, etc.) is shared among different stakeholders, and that one group does not have power at the expense of another.

Multivocality can operate, and be analyzed, both locally and globally – although it is important to understand that these arenas constitute and influence each other and the categories "local" and "global" should not be seen as rigid, simple, or non-permeable. For the purposes of this broad discussion, on local levels multivocality can refer to the idea that different (often previously marginalized) groups should have a voice in interpreting archaeological findings or, similarly, that different groups should have a role in studying and publicly interpreting history in ways which may include archaeology but is not limited to it. There are many examples of this across the discipline, in which a variety of people with different skillsets and interests have collaborated in planning museum displays, interpretive centers, web sites, and the like. In many of these examples, different perspectives (about history, about "being," about a site, etc.) are presented alongside each other, with equal standing. In global contexts, multivocality is often seen as a way to democratize archaeology itself and, even more broadly, to have a role in global justice and human rights movements. In these contexts it is seen as one way to dismantle larger forces of colonialism and is often enacted in the work that archaeologists and others do with international organizations such as UNESCO and the World Archaeological Congress. Therefore, there are important differences of scale as different archaeologists engage with the idea of multivocality. Some focus mostly on local practice, and others situate their work in broader arenas, but all modes of practice have important roles in articulating contemporary archaeological discourse about multivocality.

Some important issues and challenges arise at all scales, however. One has to do with past practices and the complicity of archaeology (and, in some contexts, anthropology) in maintaining dominant hegemonies and imperialist power structures. Put simply, those who have been oppressed in the past, or who are still oppressed today, often see archaeology as part of that oppression and thus suspect. Another has to do with relativism. Is any perspective – any truth, any voice – as legitimate as another? How does any person, or group, evaluate differing truth claims? Most archaeologists are willing to engage respectfully with those whose epistemological and ontological perspectives are widely different from their own, and some archaeological approaches emphasize, more than others, the value of multiple lines of evidence when interpreting material remains. However, few archaeologists are willing to reject empiricism altogether. Despite this, many have found ways to have positive, multivocal, and democratic conversations with those who have different perspectives. Most recently,

archaeologists who are, themselves, members of indigenous groups have explored approaches which neither reject nor privilege Western mainstream approaches but instead create new, hybrid approaches which allow for the idea that different "truths" can be equally true, even if they are not commensurable in a scientific sense (Atalay 2008).

In all of these approaches to multivocality, the ideal scenario, as noted above, is usually defined as one where there is *mutual* empowerment between different groups. Obviously this ideal is difficult to achieve. In a global context, multivocality has mostly to do with eliminating the power imbalances caused by centuries of domination by "the West." In commercial archaeology (Cultural Resource Management, known as "CRM") contexts worldwide, power is almost always weighted towards professionals, policy makers, and private property advocates (such as property developers) who are in turn subject to (and supportive of) the power held by politicians. In other contexts, especially over the last couple of decades, some tribal/indigenous groups now have real power with respect to some issues (although it is important to note that some groups do not; see the sections of this volume that deal with indigenous legislation in different contexts). In addition, issues surrounding class, race, and gender, as well the legislative and cultural specifics that emerge from different legal, governmental, and geographical contexts, complicate and influence who has the "real" power in any given situation. Despite these realities, many archaeologists across the globe have attempted to create situations in which multiple voices and narratives can at least be expressed and where there is genuine, reciprocal dialogue between various people and roles. These sorts of projects are sometimes enacted as "collaborations," not as multivocality per se – in practice, the terms and ideas are often conflated.

Examples

Writing about multivocality within archaeology tends to fall into three different and often overlapping areas: theorizing multivocality, operationalizing multivocality, and, more recently, evaluating multivocality. Much of the writing by the various postprocessual archaeologists can be seen as theorizing multivocality (as well as theorizing as the other key ideas in postprocessualism). The literature on this is huge; one example would be Hodder and Hutson (2004) but see "Further Reading" for more. Several of the writers who are interested in theory have also attempted to operationalize multivocality – that is, to apply specific multivocal strategies to specific projects. Two of these would include Hodder (2000) and McDavid (2002).

Other writers have concentrated on operationalizing – that is, on practice. Most public archaeology writing over the past two decades would fall into this category (see "Further Reading"). Although some of the individual contributions to these volumes discuss the author's underlying theoretical assumptions, for the most part these case study volumes focus on practice. Practice-oriented multivocality work would also include that done by countless agency, academic, nonprofit, and museum archaeologists who now routinely acknowledge (and sometimes seek) multiple voices to engage with, even when they do not (or sometimes cannot) write about this aspect of their practice. Some of these operate in the CRM field, where opening up their practices in an explicit way can be difficult, given the push-pull of client interests and politics. In these cases, multivocality often exists, but in a more hidden way that is seldom written about in public forums (but see (LaRoche 2011) for an important example where it is).

Although the focus in this article is on multivocality, it is important to be aware that many of the ideas mentioned above as, together, informing a postprocessual approach (reflexivity for example), usually occur together. That is, archaeologists who seek multivocal strategies usually hope that their work will be reflexive, open, relevant, collaborative, and so on. A useful idea to take on board, if one is attempting to develop strategies along these lines, is the "collaborative continuum" suggested by Chip Colwell-Chanthaphonh and T. J. Ferguson (2008). Here one accepts that even though all projects will fall at one point or

another along a continuum of collaboration, multivocality, mutual empowerment, etc., it is still worthwhile to make an effort that works *towards* these things. Therefore, with respect to multivocality, one may find, close to one end of the spectrum, "top-down" outreach efforts aimed mainly at simply sharing archaeological information with different groups. Near the other, one would find projects which are truly multivocal and mutually empowered in all stages of the project – from planning to implementation to interpretation and public interpretation. Stephanie Moser and her colleagues, at the University of Southampton in England, have developed a useful methodological framework for this type of work (Moser et al. 2002). Although it was written specifically for a volume on "community archaeology," it is applicable to a broader discussion of multivocality as well. The introduction to the same volume, and the case studies, is also very useful.

In these sorts of attempts, sharing "real" power is seen as preferable. How this is defined, however, and the degree to which it can be achieved are extremely context-specific. Strategies that are useful for one project may be less or not at all useful for another – there is no one-size-fits-all method for "what works." Even so, it is fair to say that it is now relatively commonplace for archaeologists to make an attempt, at least, to open their work to other voices and perspectives. Again, the idea of a continuum is useful here.

Even when archaeologists attempt to create multivocal projects at the mutually empowered end of the spectrum, the result is not always positive. As noted above, each party has to evaluate the truth claims of other parties and to have a basic acceptance that multiple, even contradictory, truths can exist in any given project or any social or political contexts (even if one does not accept the hybrid approaches noted above). One only has to look at the fraught and bloodstained histories that exist in many parts of the world to know that this is often difficult (Meskell 1998). In order to create successful multivocal projects, archaeologists have experimented with different approaches – philosophical pragmatism (Preucel and Bauer 2001; McDavid 2002; Saitta 2007), participatory action approaches (Pyburn 2009), applied and "activist" anthropology (Shackel and Chambers 2004; Stottman 2010), community archaeology (Marshall 2002), and others. It is not unusual for writers who are allies with respect to the "big" goals of postprocessual practice (to be multivocal, open, reflexive, collaborative, etc.) to have different methodological, philosophical, or theoretical approaches. It is also very common for the same people to contribute to different edited volumes subsumed under different overall approaches.

Future Directions

The most recent writing about multivocality attempts to evaluate it, not to simply describe or celebrate it (both of which are common to much of the earlier writing – critical analysis of multivocality has been rare). Evaluative, critical pieces examine when multivocality works, when it does not, and why this is the case either way – and avoids the taken for granted that multivocality is always a good thing. One of these new publications, targeted specifically towards the issue of multivocality, is Habu et al. (2008). In this volume various authors (from Europe, North American, Latin America, and Asia) look critically at the roots of multivocality (as noted above, the intellectual traditions of "the West") and question whether it is always useful or even appropriate. As Hodder put it in his contribution to this book:

> . . .achieving the participation of marginalized groups involves a lot more than providing a stage on which they can speak. It involves changing practices and contexts so that disadvantaged groups have the opportunity to be heard and responded to. It involves trying to move away from the methods and principles that are attuned to the Western voice. It involves ethics and rights. (Hodder 2008: 196)

Archaeology as a multivocal exercise is still relatively new. Typically archaeological information has been, and still is, both created and presented in authoritative ways by archaeologists who want to promote archaeological agendas (such as research or stewardship). Therefore, those who attempt to enact multivocal

archaeology projects work against a long history of archaeological discourse which has not encouraged debate and critique – much less the mutual sharing of power. Multivocal archaeologies are, therefore, often difficult, and attempts to create them are often unsuccessful.

Even so, as more and more models of this sort exist, it is likely that more and more *will* be seen as successful by both archaeologists and their publics – they will move beyond dialogue (Hodder 2008) to create new and different ways of creating and implementing new archaeological projects, new ways of interpreting archaeological sites, and new ways of expressing "truth." In short, consideration of the issues involved in multivocality, either as a theoretical idea or as a framework for practice, is a necessary part of conducting an ethical archaeology in the twenty-first century.

Mulvaney, John

Jordan Ralph
College of Humanities, Arts and Social Sciences, Flinders University, Adelaide, SA, Australia

Basic Biographical Information

Derek John Mulvaney (Fig. 1) is an Australian archaeologist and is often referred to as the "Father of Australian Archaeology". Mulvaney was born in 1925 in Yarram, Victoria, Australia, and spent most of his youth and teenage years in the regional Victorian towns of Yarram, Albert and Rainbow. He attended the Rainbow Higher Elementary School until he finished the tenth grade, when he moved closer to Melbourne with his family so that he could attend high school in Frankston. Once Mulvaney completed the 11th grade at Frankston High School, he registered as a student-teacher and worked at the Frankston Primary School for a brief period during 1942–1943.

Mulvaney, John, Fig. 1 Derek John Mulvaney

Growing tired of teaching, Mulvaney joined the Air Training Corps in the hope of being a navigator for the Royal Australian Air Force (RAAF). He was enlisted in Somers Initial Training School in 1943, soon after his 18th birthday, where he trained as an aircraftsman second class. During further training in Canada, Mulvaney was promoted to the rank of Pilot Officer of the RAAF and was posted in England for 2 years during the end of the Second World War. Mulvaney was 20 by the time he returned to Australia and he says that the experience was essential to his adulthood as he "departed for Canada as a country lad and returned a serious adult. [His] experience fostered maturity and determination, infused with a romanticism for the past" (2011: 38).

Upon his return from deployment during the Second World War, Mulvaney enrolled in the History department, the University of Melbourne, during 1946–1948. Mulvaney studied British, Australian, and ancient European history as an undergraduate and undertook a master's degree, for which he received a first, for his study on ancient Britain. It was during his university years and his tenure as a university tutor (1949–1951) that Mulvaney was first introduced to archaeological field work and excavation. After receiving the result of his master's research, he applied for a traveling research scholarship in the Australian National University (ANU), which was only usually awarded to advanced researchers. ANU granted Mulvaney a scholarship on the condition that he enrolled for an undergraduate degree at the university he chooses. The University of Cambridge was the most attractive to Mulvaney because the subjects offered coincided with his

interests and the demand for an Australian archaeologist: the Paleolithic. Between 1951 and 1953, Mulvaney studied archaeology at Cambridge and took part in and conducted several excavations. Following his graduation from Cambridge, he was offered a post in Auckland, New Zealand, to set up a university archaeology department; however, he declined as he had already received a position in his old department at the University of Melbourne. Jack Golson, a colleague of Mulvaney, took up the post in Auckland instead.

Mulvaney married Jean Campbell during February 1954 and they were blessed with six children in the following decades. During this decade, Mulvaney continued to support his family by working at the university where he was inspired by the research into ancient Australia by museum curators, Fred McCarthy, Norman Tindale, and Edmund Gill. Mulvaney was determined that Aboriginal occupation of Australia was much older than European Australians believed; however, he had trouble convincing many people. Mulvaney decided that excavation and analysis was the only way to prove the claims of McCarthy, Tindale, and Gill, and he put this into practice at an excavation of Kenniff Cave in Queensland. The radiocarbon dating of charcoal recovered from Kenniff Cave returned dates of 16,000 BP, which Mulvaney claims to be "one of the most stimulating episodes of [his] career" (2011: 113).

Made clear by the persistent thievery and "collecting" that occurred on sites that he excavated, such as Fromm's Landing in South Australia, Mulvaney strongly believed that Australia's heritage legislation needed to be updated and enforced. Mulvaney became an advocate for the legislative protection of Aboriginal cultural heritage throughout his career. After witnessing the destruction of an Aboriginal rock-art site in Tasmania, 1962, Mulvaney successfully campaigned with Rhys Jones for the Tasmanian government to establish heritage legislation, which was put in place in 1975. Departing the University of Melbourne in 1964, Mulvaney took up a new post with the Prehistory department at the ANU and was elected as a council member of the Australian Institute of Aboriginal Studies (AIAS). This new post allowed him to research Australian archaeology without the time and facility restrictions he experienced at the University of Melbourne. Mulvaney became an executive member and chair of the Prehistory Advisory Committee in 1965 and edited a volume in Australian archaeology on behalf of the AIAS in 1968. Mulvaney published his first book on Australian archaeology with Thames and Hudson in 1969, titled *The Prehistory of Australia*, and Penguin Books published a revised second edition in 1975. This book was the first to focus on Aboriginal history before European settlement. As part of the AIAS council, Mulvaney was involved in the 1975 Australian and New Zealand Association for the Advancement of Science conference in Canberra where the Australian Archaeological Association was formed.

Teaching commitments was part of a multitude of burdens that Mulvaney faced in the late 1970s and early 1980s. His commitments to several councils, such as the Heritage Commission, the Interim Council of the National Museum of Australia, the AIAS, and the Joint Academics Committee on the Protection of Prehistoric Places, left little time for anything else, except for his family, for which he always found the time (Mulvaney 2011: 225). In 1977, Mulvaney was the chief Australian delegate to the UNESCO meeting in Paris, which determined the criteria for World Heritage listing. Mulvaney says that he "believe[s] that the criteria that we drew up… were sound ones, providing equal status for natural and cultural values," however, he has become disillusioned with the current status of World Heritage listing and says that it is "out of hand" (2011: 219–220).

Before his retirement, Mulvaney was inducted as a Companion of the Order of St Michael and St George in 1982. Mulvaney retired from the ANU at the end of 1985, and in the early stages of his retirement, he wrote a book that investigated Aboriginal encounters with non-European people, entitled *Encounters in Place*, which was published in 1989. In 1990, the ANU inaugurated the annual Mulvaney Lecture, which honors Mulvaney's career and contribution to Australian

archaeology. Notable events in Mulvaney's retirement include becoming the chair of the new Australian Capital Territory Heritage Commission during 1986–1989, being elected as secretary of the Australian Academy of the Humanities between 1989 and 1996, and being inducted as an Officer of the Order of Australia in 1991. During the late 1990s and throughout the 2000s, Mulvaney continued to write about his career, Australian archaeology and early Australians; the third edition of his book *The Prehistory of Australia* was revised with coauthor Johann Kamminga in 1999 and released as *Prehistory of Australia*. Mulvaney illustrates that his career has contributed to "a story that places Aboriginal societies at both the beginning and centre of Australian history" and that "[his] trowel and [his] pen have contributed to overcoming that silence of ignorance and prejudice" (2011: 332).

Major Accomplishments

The major accomplishments of John Mulvaney include being the first professor of archaeology with direct involvement in Australian prehistory; Establishing Aboriginal occupation of Australia during the Pleistocene; Being a mentor and/or teacher of most prominent Australian archaeologists; Helping secure the Willandra Lakes Region and Kakadu on the World Heritage List; Being a pioneer in engaging with Indigenous Australians about their cultural heritage; Successfully campaigning for the legislative protection of Aboriginal and Australian cultural heritage; Long-term commitment to Australian archaeology by serving on and chairing several of Australia's councils for heritage.

Introduction

Mummies are one of the most appealing subjects within the field of archaeological science, not only to the general public but also to academics. Due to their unique preservation status, mummies can provide specialist avenues to historical and scientific knowledge of the past that cannot be obtained by other research methods. Thanks to the interdisciplinary work carried out by teams of scholars representing a great variety of research fields, mummies have provided us with unique opportunities to better understand the peoples and societies of ancient and later times (Cockburn et al. 1998).

Definition

Mummies are human (or animal) remains displaying preserved non-bony tissues. The term *mummy* is a derivation from the Old Persian word, *mumeia*, or *mum*, meaning bitumen or pitch (Lynnerup 2007). We call them mummies when a reasonable amount of soft tissue is preserved to an extent that the skin and/or hair, muscles, ligaments, tendons, or even internal organs can be observed (Lynnerup 2007).

Historical Background

In the fourteenth to fifteenth centuries, Egyptian mummies were imported into Europe for sale as medicines (Pringle 2001). In 1798, scientists accompanied Napoleon Bonaparte's invasion of Egypt to investigate one of the greatest civilizations in the ancient world (Lynnerup 2007). Inspired by mummies' academic significance and general curiosity value, museums in Europe and America started to import mummies for display in their collections (Pringle 2001). Soon thereafter, the initial stages of serious mummy science were led by pioneering scholars. Thomas Joseph Pettigrew's *A History of Egyptian Mummies* in 1834 is generally regarded as the beginning of serious systematic research on mummies (Aufderheide 2003; Lynnerup 2007), while the first examination using X-rays was carried out as early as 1896 (Cockburn et al. 1998). In the early twentieth century, Sir Grafton Elliot Smith, one of the most acclaimed Egyptologists worldwide, created a milestone in the history of mummy research, by being the first person to use X-ray to examine a mummy. When the tomb of Tutankhamen was discovered, Grafton was responsible for the examination of his preserved body. He used the same approach that is taken today using more sophisticated techniques (CT, MRI, and so on). In the 1970s, the mummy of Pharaoh Ramses II was examined by a team of over 100 scientists. The first computed tomography (CT) scanning of a mummified specimen was carried out in 1976 (Chhem and Brothwell 2008), while the Manchester Mummy Project released its findings in a series of studies presented to the public in 1979. By then, the concept of interdisciplinary research was established within the field of mummy studies (Lynnerup 2007). It is also noteworthy that, since the 1990s, a great number of international symposiums and conferences have hosted researchers to exchange information on various mummy investigations (Pringle 2001; Lynnerup 2007). Nowadays, many new biotechnological tools continue to be applied in mummy studies worldwide.

Key Issues/Current Debates

Research Techniques: The new research techniques recently introduced in mummy studies are providing access to the great stores of scientific information lurking within mummified tissues. Morphological inspection, the most conventional and simplest technique, has been widely utilized in anthropology so far (Aufderheide 2003). Histology is useful as well, particularly in determining the degree of preservation as well as in identifying specific signs of disease such as atherosclerosis, liver cirrhosis, neoplastic lesions, and others (Aufderheide 2003; Lynnerup 2007). A highly significant finding of electron microscopy is that no matter how well-preserved the mummies were, most mummified tissues were composed mainly of collagen (Lynnerup 2007). A comprehensive and detailed knowledge of mummies was gained by performing full autopsies (Aufderheide 2003), which also enables acquisition of rich scientific information on mummification procedures (Lynnerup 2007). However, these advantages notwithstanding, "to autopsy or not" has long been the question of two opposing groups: one argues that autopsy is indispensable to serious, comprehensive scientific analysis; the other argues that autopsy is unnecessarily invasive and destructive (Pringle 2001; Lynnerup 2007).

Radiology: Of all noninvasive techniques, radiographic tools are the most widely recognized for their scientific utility (Chhem and Brothwell 2008). Sex, age, and other physical traits can be estimated by radiological analysis (Lynnerup 2007). Through radiology, moreover, pathological signs such as degenerative changes and traumas can be accurately identified (Lynnerup 2007). CT radiography enables effective assessment and diagnostics for mummies by means of image reconstruction (Lynnerup 2007). One such example is the prehistoric mummy found in a Tyrolean Alps glacier, also known as the Tyrolean Iceman or "Ötzi" (see "Ötzi, the Iceman," below). Upon CT scanning, the mummy's anthropological traits could be comprehensively evaluated; even a probable cause of death was identified: an arrowhead lodged in the left shoulder area (Fleckinger

2014). Like CT scanning, magnetic resonance imaging (MRI) has been widely employed in mummy research (Chhem and Brothwell 2008). Although CT diagnostics have become the routine tool of mummy studies, we often are faced unpredicted problems: the possible misdiagnosis of mummified structures on CT images. As each mummified organ undergoes serious taphonomic changes due to displacement and dehydration after death, the interpretation of CT images of mummified remains was always challenging even to expert radiologists (Aufderheide 2003). Based on this premise, a *post-factum* autopsy was sometimes necessary to confirm the nature of the mummified structures on radiological images (Kim et al. 2017). By this procedure, the risk of data misinterpretation could be reduced; and the accuracy of the diagnosis was improved. Pathological changes in each mummified organ could be more certainly diagnosed by the accumulated data of CT diagnostics (Kim et al. 2017).

Craniofacial Reconstruction (CFR): The mummies' reconstructed portraits provide us with the chance to see their physical appearance. CFR is a forensic technique that has primarily been applied to identify mummies' antemortem faces. It entails two main steps: first, the skull model is reconstructed by CT images to be used as a template for CFR of mummies (Lynnerup 2007); second, the data are post-processed by an advanced computerized system. By the procedure, the face can be recreated as a reliable reference for the depiction of a mummy's figure (Lynnerup 2007).

Endoscopy: This technique, originally developed for clinical medicine applications, is another nondestructive investigative tool utilized in mummy studies (Pringle 2001). Unfortunately, the internal organs of mummies, as viewed by endoscopy, usually bear little resemblance to those of living individuals. Endoscope insertion into internal cavities is not easy either, as there is no or little room due to the collapse of internal organs (Aufderheide 2003). Moreover, due to the brittleness of dried mummy tissues, sampling with steel biopsy jaws also is challenging (Aufderheide 2003). Overall, endoscopy could not be a "gold standard" for investigation of mummified remains though it is certainly useful in some exceptional cases.

Chemical Analyses: Stable isotope analysis of bone collagen is frequently applied in order to reconstruct the dietary history of mummified subjects (Lynnerup 2007). For such analyses, hair samples are more commonly used. As hair grows at a constant rate and is not remodeled after it forms, the attributes of hair enable consideration of dietary intake patterns in a detailed chronological fashion (Lynnerup 2007). Studies of proteins, lipids, and trace elements also are important in mummy studies. Alcohol or other drug use (e.g., cocaine or nicotine) could be detected by chemical analysis of mummies (Lynnerup 2007).

Ancient DNA (aDNA) Analysis: Since the first scientific report of ancient DNA (aDNA), genetic information continues to be acquired from prehistoric or historic mummies (Lynnerup 2007). The preservation status of aDNA in mummy tissues is far better than in any other ancient specimens; and among mummies, permafrost specimens have better-preserved aDNA than those found in arid regions (Gilbert et al. 2007). Notwithstanding the achievements of the past decades, the authenticity of aDNA analysis has often been seriously challenged as a result of contamination of samples by modern DNA from the environment. Cross-contamination between mummy specimens also has been an issue of concern. Strict criteria for the handling of samples thus have been introduced and enforced to minimize the possibility of contamination in aDNA analysis. The reliability of such studies has improved since the recent introduction of the advanced New Generation Sequencing (NGS) technique, which provides a more sophisticated means of checking for specimen contamination (Orlando et al. 2015). Ancient DNA analysis can be essential to the confirmation of nongenetic diagnoses of ancient diseases as well as to the understanding of the evolutionary processes of pathogens by gleaning genetic information from mummies (Lynnerup 2007).

Mummification Processes: How mummification occurred in various natural environments and cultural contexts is of central importance to

researchers. The mechanisms whereby tissue degradation was hindered and bodies preserved during the mummification process have been eagerly sought out by scientific studies performed over the course of several decades (Aufderheide 2003). Both natural and artificial mummification processes have been revealed so far (Lynnerup 2007). The former is induced by extremely hot, dry, or cold conditions, without any techniques of manipulation by humans. These mummies have been found in arid environments such as Taklimakan, Nubia, the Canary Islands, Chile, and Peru, as well as the American Southwest (Cockburn et al. 1998; Lynnerup 2007). Permafrost regions such as Greenland, the Andean highlands, Siberia, Canada, Alaska, and the Tyrolean Alps also are conducive to natural mummification (Lynnerup 2007). Meanwhile, artificial mummification is facilitated by embalming practices that must have originated from ancient knowledge about the long-term preservation of fish or meat. Embalmers removed internal organs and treated bodies with substances including natural salt (natron) and resins, among others (Cockburn et al. 1998).

Paleopathology: New biological techniques enable more precise tracing of the pathologies of mummified people (Cockburn et al. 1998). With these new approaches, mummy studies can demonstrate various signs of ancient diseases and causes of death that could not be revealed by the simple examination of skeletal remains. For example, careful examinations can yield evidence of traumatic wounds and pathologies that often are very illuminative of mummified people's diseases (Aufderheide and Rodriquez-Martin 1998; Lowenstein 2004). Mummies often showed forensic traces of execution or of victimization by violence (Lynnerup 2007). Pathologies of the cardiovascular system (atherosclerosis, myocarditis, pericarditis, coronary artery disease) and pulmonary system (anthracosis, emphysema, hemorrhage) often are discovered in mummies (Aufderheide 2003; Lynnerup 2007). Calculus formations in the biliary as well as urinary systems have been observed in mummies (Lynnerup 2007). Compared to modern people, tumors have been rarely reported from mummies, possibly due to the relatively shorter life expectancy or fewer carcinogenic factors prevailing in ancient environments (Aufderheide and Rodriguez-Martin 1998). Infectious diseases have been traced by analysis of aDNA and/or histology. In the case of tuberculosis, for instance, the histological diagnosis of acid-fast bacilli in mummified tissues has proved useful in detection of the ancient genome of the tubercle bacillus (Lynnerup 2007). Syphilis and smallpox have also been identified in mummies through the gross examination of lesions as well as by aDNA analysis (Lynnerup 2007).

Parasitology: The study of ancient parasites is carried out to understand parasitism throughout history. It illuminates not only parasitism itself but also its sociocultural aspects by showing the interactions among parasites, hosts, and environments. Enteric helminth infection has been diagnosed by microscopic examinations of mummy coprolites. Ancient parasite eggs also have been subjected to aDNA analysis. Among the most commonly identified ancient parasite species are nematodes (*Ascaris*, *Trichuris*, hookworms, etc.) and trematodes (*Clonorchis*, *Paragonimus*, etc.). Notably, the study of hookworm and whipworm eggs has contributed constructively to the debate on how human beings could pass from Old World Siberia to New World America via the Bering land bridge (Aufderheide and Rodriquez-Martin 1998). Other important subjects of parasitological study have been trypanosomiasis, malaria, leishmaniasis, and schistosomiasis (Lynnerup 2007). Louse and flea infestations were also reported from pre-Columbian Peruvian, Aleutian, and Greenland mummies (Lynnerup 2007).

Everyday Life: One of the most fascinating aspects of the scientific investigation of a mummy is that we can catch glimpses of the ancient individual's everyday life. For instance, the presence of anthracosis in mummy lungs has suggested the possibility that sooty air was inhaled while living in an enclosed space with a fireplace or oil lamps installed (Aufderheide 2003). Finding the *Trichinella* parasite in a Greenland child mummy's muscle revealed the historical origin of an old custom of that region, according to which the season's first catch of walrus was eaten raw. Due to the *Trichinella* parasite's ability to infect through the ingestion of raw walrus meat, this

custom can be traced back to at least the sixteenth century, the time at which the mummy was estimated to have lived. In addition to many mummy tattoos reported worldwide (Krutak 2013), other cultural ritualistic markers such as earlobe piercings and male circumcision also have been reported, based on examinations of mummies of ancient Egypt as well as South America (Aufderheide 2003).

Ethical Issues: Mummy research has sparked ethical controversies about the removal of mummy clothing, adornments, burial shrouds, etc. as well as the display of bodies in public spaces (Day 2014; Moissidou et al. 2015). Strict ethical protocols have been established to guarantee the respectful treatment of mummified corpses (Kreissl Lonfat et al. 2015; Kim et al. 2017). Most fundamentally, researchers must obtain the requisite permissions before undertaking any mummy examinations. Even in cases where family members, descendants, or relevant agencies generously allow such studies, other ethical issues surrounding the conduct of autopsies come into play. Actually, as the mummified corpse is the vestige of a living person, unnecessary damage should always be avoided as much as possible (Kim et al. 2017). Furthermore, whereas scientists typically prefer autopsy for more detailed research on mummies, archaeologists and curators are less happy with this invasive technique. Some diagnostic tools used in clinical medicine, such as endoscopy and CT, have thus been gradually introduced into mummy studies as noninvasive alternatives to autopsy (Lynnerup 2007). In specific circumstances such as rescue archaeology, however, the usual consensus on the use of noninvasive analysis often has to be abandoned. The choice of an invasive or noninvasive technique as the principal research tool will always accord with the circumstances of an individual case in terms of the best balance of ethics and efficiency (Kim et al. 2017).

International Perspectives

Egyptian Mummies: Ancient Egyptian mummies are the most famous and best studied among those that had formed "artificially" as the result of the employment of specific embalming techniques (Cockburn et al. 1998). To the ancient Egyptians, the body was to be manipulated so as to be rendered incorruptible and thus indistinguishable from the living appearance of that person. This was central to ancient Egyptians' ideology concerning the afterlife (Lynnerup 2007). Bodies dating to Egypt's pre-dynastic period have sometimes been found desiccated and mummified even without having undergone any embalming process, due most likely to the sand's wicking action secondary to its porosity (Aufderheide 2003). Artificial mummification in ancient Egypt was developed from experience. As far as the mummification rites of the ancient Egyptians are concerned, our current knowledge is significantly indebted to Herodotus (Cockburn et al. 1998). There are, however, many variations to this theme. According to Herodotus, one of the Egyptians' main embalming techniques was the removal of all body organs and fluids. The brain tissue and other internal organs were extracted and then deposited in canopic jars. The body fluids were also removed using salts (natron) to hinder putrefaction. All of the embalming rites collectively were developed to advanced levels over the course of centuries (Lynnerup 2007). The complete embalming process can be summarized as follows (Cockburn et al. 1998):

(1) The corpse was laid on a table.
(2) The brain was removed through the nose by means of a hooked metal rod.
(3) The abdominal organs were extracted through abdominal incisions (usually on the left side), and the thoracic organs were removed through incisions made in the diaphragm.
(4) The body cavities and viscera were sterilized.
(5) The viscera were dried and treated with resin, wrapped in linen, and placed in canopic jars.
(6) The thoracic and abdominal cavities were stuffed temporarily with packing materials, preparatory to a 40-day process of complete desiccation.
(7) After completion of the drying process and the subsequent removal of the packing materials, resin or resin-impregnated cloth was

packed into the cranium, while the other body cavities were stuffed with linen cloth and bags.

(8) The body was anointed with fragrant materials; the orifices of the head were packed with wax or resin-soaked linen. Molten resin was smeared over the entire body to act against the reentry of moisture and to strengthen the skin.

(9) The body, finally, was wrapped in linen bandages wherein amulets and other pieces of jewelry were placed.

The overall process of embalming took 70 days. Macroscopic, histological, and endoscopic examinations have revealed several pathological signs in Egyptian mummies. The calcified ova of *Schistosoma haematobium* have been observed in mummy kidneys, which must have caused hematuria among living ancient Egyptians. Upon radiological examination, arthritis, arterial calcification, and bone infarction have been found. Harris lines, a sign of intermittent disease or malnutrition, could be identified in about 30% of radiographs of Egyptian mummies' tibiae, which indicates generally poor nutrition among ancient Egyptian children and adolescents (Cockburn et al. 1998).

Ötzi, the Iceman: On September 19, 1991, this famous mummy was found in the Ötztal Alps. Along with this mummified man, a number of cultural artifacts also were collected, including grass string and matting, a birchbark container, axe, dagger, sheath, longbow, quiver, net, fur cap, backpack, shoes, and coat and leggings made of domestic goat skin, among others (Fleckinger 2014). Based on the results of archaeological analysis and radiocarbon dating, this man is estimated to have lived between 3350 and 3100 BCE (the late Neolithic or Cooper Age) (Fleckinger 2014). The mummy was initially investigated at the Institute for Forensic Medicine in Innsbruck, Austria, and subsequently at the Institute for Mummy Studies at the European Academy (EURAC) in Bolzano, Italy. Through these analyses, many details were revealed, including brown eyes, 50 kg of weight, 45.7 years of age, and degenerative changes in the joints (Fleckinger 2014). Ancient DNA (aDNA) analysis can reveal much information that is unobtainable by any other means (Fleckinger 2014). For instance, 96% of his nuclear genome could be sequenced. His Y chromosome haplogroup was G2a2b, now very rare in Europe and mainly distributed in Sardinia and Corsica. He also had a genetic predisposition to cardiovascular diseases (atherosclerosis), and aDNA analysis also revealed that Ötzi was lactose intolerant (Keller et al. 2012). The Iceman's body displayed over 50 tattoos, which might correspond to acupuncture pressure points (Samadelli et al. 2015). CT also was employed in studies of Ötzi, the most significant result of which was the identification of an arrowhead in his left shoulder, which was concluded to be the cause of his death. It appears that the Iceman was shot from behind, by an arrow shot from a considerable distance (Fleckinger 2014). Unfinished arrows and a half-completed bow indicative of a rearming process, combined with his fractured ribs, suggest that he had been involved in a violent encounter. This study reveals the personal tragedy that the Iceman experienced (Spindler et al. 1996; Fleckinger 2014). Ötzi currently resides in Bolzano's South Tyrol Museum of Archaeology.

Mummies in Catacombs and Crypts: Mummies have been discovered in churches and convents of Europe, with the largest number being found in Italy (Aufderheide 2003; Lynnerup 2007). Several hundred mummified individuals, for instance, are maintained in the Catacombs of the Capuchin Brothers in Palermo, Sicily. These mummies were found in burial contexts ranging from the medieval period through to the renaissance and up to more recent times (Cockburn et al. 1998). In general, church mummies can be divided into two different categories: natural and artificial. The natural mummification that occurred in Southern Italy was caused by favorable climatic and environmental conditions, further facilitated by drainage of cadaveric fluids, as carried out in the crypts of churches over the course of several months. In some cases, cadaveric liquids could be collected in large stone or pottery vases. Processes of evisceration or injection with chemical preservatives, in contrast, determined artificial mummification.

Bog Bodies: In Northern Europe, unique mummies known as "bog bodies" have been

discovered. These bodies had been mummified as the result of having been buried in the acidic-anaerobic environment of peat bogs (Lynnerup 2007). Sphagnan, a polysaccharide compound of the sphagnum mosses present in such bogs, is important to impede the decomposition of dead bodies. Specifically, by chelating calcium, sphagnan causes demineralization of the bony tissues, making bog-buried bodies lose their hardness and become pliable (Lynnerup 2007). Due to this leaching of calcium from the bones, radiographs of bog bodies are not very informative (Lynnerup 2007). Although the estimated dates of the bog bodies range from 900 BCE to 1800 CE, those representing the years 600 BCE to 300 CE attracted particular scholarly attention for having been early Germanic peoples of Northern Europe (Spindler et al. 1996). The most interesting aspect of prehistoric bog bodies is the commonly detected evidence of trauma resulting either from socially sanctioned punishment or physical violence.

Guanche Mummies: The Canary Islands archipelago was colonized following the Spanish conquest of these lands in the fifteenth century. Prior to this, aboriginal people dwelled there. The Guanche mummies of the Canary Islands that were discovered by colonizing Spaniards have long been the subjects of academic debates. In these cases of mummification, the embalming techniques employed were evisceration, sand stuffing and the use of preservatives. After being embalmed, the bodies were placed in caves on the islands (Cockburn et al. 1998).

North American Mummies: In the United States, prehistoric mummies of Amerindian peoples have been discovered in rock shelters, dry pits, or the cysts of caves and overhangs (Cockburn et al. 1998). The mummies were discovered and investigated in Texas, Kentucky, and Tennessee. Arrested growth lines showed that these individuals sometimes must have starved while alive. Dental diseases were the most consistently observed health problems among them. In Florida, the mummified brain of a hunter-gatherer, which was date-estimated to 7000–8000 BP, was discovered in a peat bog. The potential of mummy studies in North America, however, declined appreciably after the Native American Graves Protection and Repatriation Act was passed in 1990, which legislated that human remains that were discovered should be repatriated to Native American tribes.

South American Mummies: The oldest artificially created mummies in the world have been found in the Chinchorro culture along the Atacama coast in present-day Chile, dated to approximately 9000 years ago (Cockburn et al. 1998). The earliest Chinchorro mummies are those of children whose bodies were anthropogenically reconstructed after death. Their viscera and brains were removed; the legs, arms, and trunk were reinforced by sticks; and the faces were coated with thin clay and painted. The Chinchorro diet was mainly composed of marine products, followed by terrestrial meats and plants. They had very few dental cavities due to a diet low in carbohydrates and high in abrasive materials. Since these children were infected by tapeworm parasites, it is likely that they ate raw or poorly cooked fish. Later in history, ancient Peruvian sedentary farmers positioned the bodies of their dead upright while wrapping them in discrete layers of ceremonial garments and wrapping cloths. The preservation of the Middle Horizon period mummies in large bundles might have been achieved specifically via desiccation by means of natural agents and by tightly wrapped cotton layers that absorbed bodily decomposition fluids. The tradition of bundle burials continued, though regional variations in the wrapping of the cadavers have been noted. Detailed information on the final stage of Andean prehistory, which began with the emergence of the Inca Empire and ended with the Spanish conquest of 1534, has been available in the form of a rich corpus of ethnohistory written during the early stages of the colonial period. At this point, the cadaver was eviscerated and treated with certain balsamic substances to preserve it. The viscera were placed in freshly made ceramic vessels buried next to the mummy bundle. Mortuary practices clearly were conditioned to a considerable degree by social status. While the common people typically were

buried with few possessions, the bundles of the elite contained masses of textiles, instruments, and other goods. Although royal Incan mummies might have been embalmed, the detailed process employed has yet to be fully revealed. Incan mummies found in high-altitude (5200–6700 m) mountain areas are also well known. These individuals may have been intoxicated with alcoholic corn beer or narcotic coca leaves prior to being sacrificed by strangulation, or they may simply have been abandoned to die of exposure. The most famous of these mummies include the frozen Inca girl *Juanita* discovered on Mount Ampato and an 8- to 9-year-old Inca child found at 5400 m on the Cerro El Plomo peak in the Andes (Spindler et al. 1996; Cockburn et al. 1998).

Arctic and Subarctic Mummies: Postmortem degradation was hindered in the arctic and subarctic regions, by the combination of year-round low temperatures, low air humidity, high winds, and the sheltered positions of graves (Cockburn et al. 1998). A scholarly interest has been aroused due to these remains' excellent preservation status. This is particularly true in the cases of mummies found in the Aleutian Islands, Alaska, Greenland, Canada, and Siberia (Lynnerup 2007). One such example is the frozen female mummy (200–500 CE) washed out of a low beach cliff at Saint Lawrence Island (Alaska) in the Bering Sea. Pathological signs of coronary and aortic atherosclerosis, anthracosis in the lung, and a temporal bone fracture were found. Mummified people were also found in a crushed winter house in the Arctic region of Alaska. They appear to have died of *ivu*, an accident caused by the inland incursion of broken sea ice. Signs of massive anthracosis, osteoporosis, atherosclerosis, and bacterial endocarditis were discovered. The most famous Arctic mummies are those discovered at Qilakitsoq in Northwestern Greenland. These well-preserved mummies of the Thule culture, the direct ancestors of the present Eskimo population of the Eastern Arctic, likely were buried around 1475. They exhibited anthracosis, Down's syndrome, osteoporosis, nasopharyngeal carcinoma, and other diseases commonly found in modern Eskimo populations. Mummies discovered in Arctic regions provide us with special insights into the unique health and disease conditions prevalent in prehistoric Arctic ecosystems (Spindler et al. 1996).

Asian Mummies: There has been a prevailing belief that mummification does not occur naturally in East Asia due to high-humidity and high-temperature conditions coupled with the lack of any widespread tradition of artificial embalming reported for the region. However, mummies of Buddhist monks have often been reported in certain Asian countries. In Japan, self-mummification was attempted by Buddhist priests who were later worshipped in a Buddhist sanctuary (Cockburn et al. 1998). There also have been medieval aristocratic mummies (Fujiwara family) discovered in Japan. Although the exact cause of mummification in these cases remains mysterious, it is generally accepted that embalming might have been carried out. In China and Siberia, various types of mummies have been found under different circumstances. In brief, a mummified female dating to the Han Dynasty (206 BCE to 220 CE) was discovered in a Mawangdui tomb (Aufderheide 2003). Naturally mummified cases also have been found in the dry region of Loulan in the Tarim Basin, Xinjiang Province (Aufderheide 2003). Between 1929 and 1949, Rudenko investigated graves (dated to the fifth to third century BCE) in Pazyryk (Altai Mountains), located on the border between Siberia and Outer Mongolia. The mummified bodies found therein belonged to seminomadic tribes who had roamed the Siberian steppes in ancient times. The Pazyryk mummies had been artificially prepared by the removal of the brain and other internal organs. In South Korea, over the course of the past several decades, well-preserved mummies have been discovered in tombs dating to the Joseon Dynasty (1392–1910 CE). Despite their academic significance, the Joseon mummies' historical origins and related preservation mechanism(s) are still uncertain. The only fact that has been confirmed to date is that mummies discovered in the Chinese tombs of the Song, Yuan, Ming, and Qing dynasties share a structural

similarity to the Korean mummies and their tombs (Oh et al. 2017). In the wake of a series of important scholarly achievements, most researchers now agree on the academic value of mummies found in Asia.

Fire Mummies: Sometimes mummification by desiccation was achieved by a smoking treatment of the corpse. This tradition has been reported from North America as well as Oceania (Lynnerup 2007). One such example is the tattooed mummies of the Ibaloi people in the province of Benguet (Kabayan), Philippines. In these cases, mummification was most likely done through desiccation, since there was no evidence of evisceration (Beckett et al. 2017). After death, the body of the deceased was seated on a chair constructed of local materials. Then, a low fire was lit below the chair to enhance desiccation, hence the name "fire mummies." The fire must have created a microenvironment of decreased humidity and elevated temperature around the mummified body. The fire and wood smoke also would induce mummification by making the environment hostile to bacterial proliferation and insect infestation (Beckett et al. 2017).

Future Directions

Since the beginning of mummy research, many scholars have been devoted to the discovery of the key aspects of mummies and mummification worldwide. As this trend continues to develop, we must prepare for further innovation in mummy research. Most importantly, when a new scientific study on mummies is planned and then carried out, a sufficient number of ready-to-use samples should be made available. In this respect, the establishment of a tissue bank of mummified specimens might be a good way to start.

Mundo Maya

E. Christian Wells[1] and Whitney A. Goodwin[2]
[1]Department of Anthropology, University of South Florida, Tampa, FL, USA
[2]Department of Anthropology, Southern Methodist University, Dallas, TX, USA

Introduction

Mundo Maya ("Maya World"), formerly referred to as La Ruta Maya ("The Maya Route"), is a joint effort among the Ministries of Tourism from Belize, El Salvador, Guatemala, Honduras, and Mexico to promote tourism throughout southern Mexico and upper Central America. Geographically, the Mundo Maya covers approximately 500,000 km^2, encompassing all of Belize and Guatemala, the western half of El Salvador, northern and western Honduras, and the Mexican states of Chiapas, Tabasco, Campeche, Yucatan, and Quintana Roo.

The Organización Mundo Maya program works with the United Nations Educational, Scientific, and Cultural Organization (UNESCO) and other agencies to identify a wide range of cultural and natural resources considered appropriate for international tourism in this region, such as Pre-Columbian Maya ruins, Spanish Colonial towns, contemporary Maya villages, beaches, waterfalls, volcanoes, and tropical forests. By coordinating contiguous tourist destinations across national boundaries – all linked directly or indirectly to ancient and modern Maya peoples – the program seeks to facilitate the growth and development of the tourism industry, including ethnic tourism, adventure tourism, ecotourism, luxury tours, language learning, and other touristic experiences. The greater goal of the program is to strengthen local economies, assist in the planning and training of local economic development products and projects, preserve cultural patrimony and ecological resources, and advance the welfare of indigenous Maya communities.

Definition

A typical trip through the Mundo Maya (e.g., Brosnahan 1991; Knopf 1995) for a foreign tourist might begin in Cancún, Mexico, one of the largest resort areas developed along the Caribbean coast (Fig. 1). From there, one can travel inland to the World Heritage site of Chichén-Itzá and then back to Yucatan's coast to Tulum, touted as one of the most picturesque Maya ruins, set atop a steep cliff overlooking white sand beaches and turquoise waters. From Tulum, one can head south to Belize, crossing the border at Chetumal and heading on to Orange Walk to visit the Lamanai ruins, accessible only by a jungle river cruise. Heading farther south toward Belize City, one can book a tour of Altun Ha, Belize's largest Maya site. A side trip can be taken to visit the beaches of Ambergris Caye and Caye Caulker. From Belize City, one can head west to San Ignacio (a popular respite for tourists and archaeologists alike), to visit the ancient Maya city of Xunantunich and other nearby sites.

A short journey across the Guatemalan border leads to the twin cities of Flores and Santa Elena deep in the Petén jungle, which provide departure points to another large World Heritage site, Tikal. From Tikal, one can head south to Guatemala City

Mundo Maya, Fig. 1 Map of the Mundo Maya, showing a "typical" tourist route

to explore the colonial town of Antigua, the Maya markets of Chichicastenango, and the volcano-studded Lake Atitlán, surrounded by contemporary Maya villages. From Guatemala City, one can head east across the border to Honduras to visit a third World Heritage site, the ruins of Copán. Heading north from Copán to Honduras' coast, a ferry shuttles travelers to Roatán Island, which boasts access to the world's second longest coral reef – a mecca for divers and snorkelers. A short trip by plane or ship from Roatán back to Cancún completes the trip.

Historical Background

The idea of interlinking touristic experiences across the Maya region was originally introduced in the 1960s, with both the Organization of American States (OAS) and the Inter-American Development Bank (IDB) expressing interest in its promotion (Burtner 2004). However, the program did not advance until the "return to democracy" in Guatemala, with the inauguration of a civilian president (Vinicio Cerezo) in 1986. After tourism boycotts of the region by solidarity organizations

and the international media because of political unrest and human rights abuses subsided, the tourism circuit was officially launched in 1989 as "La Ruta Maya" by Wilbur Garrett (1989), a former editor of National Geographic magazine who formed La Ruta Maya Conservation Foundation and, together with Partners for Livable Places, presented the proposal to regional governments. Mexican President Carlos Salinas de Gortari convened the first meeting of the organization and, on behalf of the tourism ministry of Mexico, assumed initial leadership of the group. Amid growing economic uncertainty, tourism was viewed as a new strategy for regional economic development that moved away from agricultural exports and allowed areas without viable exports to be exploited.

The Mundo Maya concept, introduced by Guatemalan anthropologist Alberto Rivera, developed separately and with a distinct focus on "alternative" or sustainable tourism and community participation – both lacking within the originally proposed framework of La Ruta Maya. Driven by the potential for marketing and diversification of the tourism product, La Ruta Maya was transformed into Mundo Maya in 1992 (OMM 1992), with the intention of showcasing the living Maya alongside the archaeological sites of their ancestors. This move was pursued as part of an effort to attract a new type of tourist, coined the "cultural tourist," who tended to stay longer and spend more money than the average beach-going tourist (Machuca 1999). The ecological conservation goals that relied on "low-impact" tourism alternatives remained unchanged. In this plan, the Maya were portrayed as partners. However, the national ecotourism councils established to implement the goals of the program proved to be largely ineffective, encumbered by the inefficiency of government bureaucracies, and the result was an increased role for the private sector.

Between 1999 and 2003, the Mundo Maya Sustainable Development Tourism Program was established with an initial investment of US$150 million from the Inter-American Development Bank (IDB). As part of this initiative, a Technical Secretariat was created to identify priority investments, seek private sector funding for individual projects, and advance consultation and training programs to build capacity in local communities. Although regional and international funding bodies have continuously provided large sums of money through grants and loans, until recently these had been limited mainly to actions such as feasibility studies and broader organizational support. Since 2001, the IDB has been the main financier of the OMM, providing amounts that range from US$70,000 to US$40.8 million for individual projects (IDB 2003).

Key Issues/Current Debates

The success of the Mundo Maya program is uncertain. While economic growth, improved infrastructure, and the conservation of cultural and natural resources have all increased dramatically in recent years, two long-term changes to local populations have accompanied these developments. First, in packaging and branding the Mundo Maya for advertising, the incredible cultural and linguistic diversity of indigenous peoples in the region has become homogenized into a single idealized ethnic group, "the Maya" (van den Berghe 1994; Castañeda 1996), with which many local individuals do not identify (Montejo 2002; Magnoni et al. 2007). "Mayanizing' tourism as such has led to unresolved conflicts between developers, tourists, and non-Maya indigenous groups (Figueroa et al. 2012; Brondo 2013). Moreover, local communities are often considered by many to be the direct descendants of the ancient Maya civilization, an assumption that ignores a thousand years of conquest, colonialization, and incorporation into emerging nation states (Farriss 1992; Restall 2008). Distilling diversity in this way has created opportunities for ecotourism initiatives to romanticize contemporary Maya peoples as "noble savages" living in harmony with the environment, a colonialist attitude that subjects Maya communities to the state's market-based agendas (Wainwright 2011; Medina 2012).

Second, in promoting the Mundo Maya for touristic consumption, descendant communities and cultural heritage have become appropriated and highly commoditized in recent years (Medina

2003; McAnany 2016). The consequences of these ongoing processes can be devastating to local communities that increasingly experience loss of identity and cultural heritage through imposed and invented traditions, loss of participation in determining their future, loss of political and economic independence, and other forms of structural violence (Breglia 2006; Little 2008). McAnany and Parks (2012) have suggested the phrase "heritage distancing" to refer to these neoliberal processes of alienation that distance contemporary Maya peoples from their history and heritage, thereby advancing colonialist strategies to profit from tourism of the "ancient Maya" (Ardren 2004).

Future Directions

In the near and longer term, the Mundo Maya initiative will have to overcome a number of challenges if it is to be sustainable. Economic development has been uneven across the region, with some communities receiving greater emphasis than others (Brown 1999). This legacy, combined with recent "pro-poor" growth initiatives advanced by the United Nations Sustainable Development Goals (Ramos and Prideaux 2014), has contributed to the underdevelopment of non-tourist zones and has stimulated short-distance movements of increasingly larger numbers of people (Juárez 2002). In addition, the emphasis on tourism as a primary source of revenue for many communities has increased dependence on external funding agencies and multinational corporations, creating a system that is not resilient to future changes in global markets (Walker 2005). The recent violence in Mexico and the 2009 coup d'état in Honduras, for example, have had massive impacts on the tourism industry in those countries, sometimes compromising economies of the entire towns (Euraque 2010).

Perhaps the greatest challenge for the Mundo Maya is developing the capacity to adapt to the consequences of climate change over the next century, which will create social, economic, and political vulnerabilities, especially for growing urban populations. Major infrastructural changes may need to be implemented in coastal regions to counteract the damage caused by greater storm surge due to sea level rise (Wells et al. 2016). For inland regions, costs needed to mitigate the adverse impacts of increased storm frequency and intensity may escalate. This kind of long-term planning appears to be a concern of some entities involved in the organization (SECTUR 2017, 2011), yet long-standing problems with existing infrastructure have yet to be addressed in many areas of the Mundo Maya. If current trends persist, unequal access to the economic benefits of tourism development is likely to increase across social, economic, and geographic divides – contributing to the exacerbation of already existing inequalities throughout the region.

M

Murra, John

David Chicoine
Department of Geography and Anthropology, Louisiana State University, Baton Rouge, LA, USA

Basic Biographical Information

John Victor Murra (Fig. 1) (24 August 1916 [Odessa, Ukraine]–16 October 2006 [Ithaca, NY, USA]) was an American economic anthropologist who combined ethnohistory, ethnography, and

Murra, John, Fig. 1 John Victor Murra (1965). (Credit: John Victor Murra Archive, Junius Bird Laboratory for South American Archaeology, Division of Anthropology, American Museum of Natural History)

archaeology to study state societies of the South American Andes, in particular the Inca Empire (Tawantinsuyu). In his youth in Bucharest (Romania), Murra studied modern languages at the Lycée Georghe Lazer where he learned French, English, and German, in addition to Russian and Romanian. He would later develop fluency in Spanish. In Bucharest, Murra became involved in communist youth groups and was briefly incarcerated. Upon the recommendation of his father, Murra moved to Chicago in 1934 to pursue his education and lived with an uncle. There, he continued his political activism and volunteered to fight alongside the anti-fascist, Republican coalition in the Spanish Civil War (1936–1939). His military papers were issued in 1937, and in 1939, Murra was injured in combat, temporarily paralyzed, and interned in a French camp.

Upon his return to the USA, Murra resumed coursework at the University of Chicago and majored in sociology. In 1940, he participated in his first archaeological excavations as part of the Illinois Field School directed by Fay-Cooper Cole. In 1941 and 1942, Murra was hired as Supervisor for the "Project 9B-Ecuador-1941-42," one of the 11 Latin American projects under the umbrella of the Institute of Andean Research and funded in part by the Council of National Defense of the US Department of State. The field project was officially directed by Fay-Cooper Cole. Along with Field Assistant Donald Collier, Murra carried out survey and excavations in the south of Ecuador, most notably at the site of Cerro Narrío (Collier and Murra 1943). Based on his field research in Ecuador, he was invited by Julian H. Steward to contribute to the *Handbook of South American Indians* (Murra 1946, 1948).

Upon graduating with a MA in anthropology in 1942 (thesis entitled "Cerro Narrío and Andean Chronology"), Murra continued his war effort by helping administer questionnaires to Spanish Civil War veterans. The following year, he assisted anthropologist Ruth Benedict in interviewing Thai (called Siamese at the time) immigrants to the USA. He became instructor of anthropology at the University of Chicago in 1943 and also held visiting positions at the University of Wisconsin, University of Puerto Rico, and Brooklyn College until 1950. At that time, Murra was hired at Vassar College where he would teach undergraduate women until 1963. Before his hire at Vassar, he also worked in the Caribbean as part of the "Study of Man in the Tropics" program, supervising fieldwork students from various universities including Yale.

In 1956, Murra completed a PhD dissertation on "The Economic Organization of the Inca State" at the University of Chicago. His doctoral research was carried out in the New York Public Library and based mainly on published sources. Once naturalized in the USA and with a passport in hand, Murra returned to the Andes in the late 1950s. Between 1963 and 1966, he directed the multidisciplinary project "A Study of Inca Provincial Life" funded by the National Science Foundation. The project incorporated ethnohistory, ethnography, linguistics, ethnobotany, and archaeological research at Huánuco Pampa. Upon encouragements from local authorities,

Murra, John, Fig. 2 Murra at Santa María del Valle, Huánuco (1964). (Credit: John Victor Murra Archive, Junius Bird Laboratory for South American Archaeology, Division of Anthropology, American Museum of Natural History)

Murra's team also worked on the restoration of Inca masonry (Murra and Hadden 1966). From that moment onward, Murra became recognized as a leading authority on Peru and the Inca. While in Peru, he also instructed at the Universidad Nacional Mayor de San Marcos. Upon his return from the field in 1966, Murra became the first NSF postdoctoral associate at the Smithsonian Institute. In 1968, he joined the anthropology faculty at Cornell University where he taught, researched, and advised graduate students until his retirement in 1982. As Professor Emeritus, Murra continued to be active as he consulted and taught at various institutions including the Museo Nacional de Bolivia (1982–1983), Universidad Complutense de Madrid (1983–1984), Universidad de Chile (1984), London School of Economics (1987), and Universidad de Buenos Aires (1987–1988) (Figs. 2 and 3).

Throughout his career, Murra was active in various anthropological organizations including the American Society for Ethnohistory (board member [1962–1969], director [1970–1971]), the American Ethnological Society (councilor [1961–1964], director [1972–1973]), the Institute of Andean Research (director [1977–1983]), and the American Anthropological Association (president nominee). He also was a founding member of the Instituto de Estudios Peruanos and the Asociación Peruana de Antropología e Historia.

M

Major Accomplishments

Murra is most famous for his pioneering contributions to economic anthropology and ethnohistorical research in the Andes. Methodologically, he recognized the importance of colonial reports (*visitas*), brought attention to Felipe Guaman Poma de Ayala's accounts and coordinated their translation from vernacular Spanish and Quechua (Guaman Poma de Ayala 1980 [ca. 1616]), as well as approached historical documents from an anthropological perspective (Murra 1961, 1962). Murra's ethnohistorical insights have shaped the understanding of the role of craft and food production and state-sponsored settlement under the Inca imperial regime. His dissertation work on the economic organization of the Inca state led to the realization of the importance of redistributive economic systems in the Andes (Murra 1980).

Through the ethnohistorical study of kin ties and trade systems during Inca times, as well as

Murra, John, Fig. 3 Murra (center) at Muru Wayin, Huánuco, with Juan Ossio (left) and Rogger Ravines (right) (1964). (Credit: John Victor Murra Archive, Junius Bird Laboratory for South American Archaeology, Division of Anthropology, American Museum of Natural History)

fieldwork in the Huánuco region of Peru, Murra (1975, 1985) elaborated the "ecological complementarity" explanatory framework. According to this model, also known as "zonal complementarity" or "vertical archipelago," ethnic groups, or in the case of the Inca a state system, exploited various ecological niches located at different elevations along the Andean landscape. Murra imagined these non-contiguous productive regions as "islands," tied together through kinship and economic interdependencies. A classic case is represented by the Lupaca, a large ethnic kingdom centered around the Lake Titicaca that included peripheral colonies in the coastal region of northern Chile, as well as in the eastern slopes of the Andes toward the Amazonian lowlands.

Although less famous for his archaeological contributions, Murra nevertheless pioneered field archaeology and culture history in Ecuador and in the Huánuco region of the north central highlands of Peru. He directed a multidisciplinary team at Huánuco Pampa which helped train several US and Peruvian archaeologists and fueled various studies of Inca provincial life, storage, material culture, and architecture (Morris et al. 2011; Morris and Thompson 1970, 1985). The American Museum of Natural History has archives of Murra's project at Huánuco Pampa, while the Smithsonian Institute holds the bulk of his papers. Murra was a strong and early advocate of Afro-American civil rights.

M

Murray, Tim

Penny Crook
La Trobe University, Bundoora, VIC, Australia

Basic Biographical Information

Tim Murray (Fig. 1) is an archaeologist and professor based in Melbourne, Australia. His interest in the material culture of the past began as a child collecting stone tools on his family property in rural New South Wales. He was educated in Sydney and embarked on an arts degree at the University of Sydney in the late 1970s, combining philosophy, anthropology, and history. He graduated with a double honors degree in history and anthropology, exploring the life and career of Gordon Childe (anthropology) and nineteenth-century race theory (history). After fellowships in Cambridge and the University of Arizona, he returned to Sydney to complete a doctoral dissertation, entitled *Remembrances of Things Present:*

Murray, Tim, Fig. 1 Tim Murray

Appeals to Authority in the History and Philosophy of Archaeology.

Tim Murray joined Professor Jim Allen in his newly formed archaeology department at La Trobe University in Melbourne, Australia, in 1986 and was appointed to the Chair on Allen's retirement in 1995. He became Head of the School of Historical and European Studies in 2001 and Dean of the Humanities and Social Sciences in 2010. At this time he was appointed Charles La Trobe Professor in recognition of his distinguished service to the University in research. He stepped down as Dean in 2014 and has returned to research.

Throughout his career, Tim Murray has pursued ambitious academic research while managing senior administrative duties. He remained active and engaged in the international research community as a research fellow and has held visiting professorships in France, the United Kingdom, the Netherlands, Sweden, the People's Republic of China, and the United States of America. He was made a Fellow of the Society of Antiquaries of London and Australian Academy of the Humanities in 2003. He was awarded a Doctor of Letters by La Trobe in 2015 in recognition of his contribution to archaeological theory, historical archaeology, and the history of archaeology.

Major Accomplishments

Tim Murray is best known as a theoretical archaeologist. In the 1980s and 1990s, he was one of a small group of archaeologists instrumental in focusing on the importance of temporality in the archaeological record that has come to be known as time perspectivism (Murray 1999a). He has been a vocal critic of theoretical approaches that reduce archaeology to a kind of "paleoethnography" by adopting models from anthropology with little consideration about how to adapt these to make them more appropriate to prehistoric archaeological contexts (Lucas 2007: 156). Throughout his career, these concerns have underpinned a broad engagement with all levels of archaeological inquiry, its history, and politics.

His early research on the prehistory of Australia and the Pacific was in the field of settlement patterns and frontier modeling. He has conducted pioneering research into contact societies and the history of the Van Diemen's Land Company. Following a dispute with traditional owners in Tasmania in the early 1990s, his contentious pursuit of access to archaeological data drew global attention to the negotiation of cultural rights of archaeological recourses. Many years after the resolution of the debate (Lucas 2007: 156), Murray continues to comment on the maturing relationship between archaeologists and traditional owners of Australia's prehistoric archaeological information (Murray 2011).

In recent years Murray's exploration of the archaeology of the modern city has fostered rich, data-driven contributions to the histories of working-class Melbourne and Sydney, which have significant global implications. This work is complemented by Murray's multi-scalar approach to the analysis of the city (known affectionately as the telephone dial, Murray and

Mayne 2001: 104), where the dynamic intersection of historical and archaeological records of "vanished communities" and urban landscape frames has underwritten new histories of the modern city. These research projects into the recent past have also spawned his current interest in transnational archaeologies, which are the subject of the series of Smuts lectures delivered in Cambridge in 2006.

A deep interest for the theoretical development, industry, and social orders of the nineteenth century underlies much of Murray's research into the historiography of the discipline of archaeology. He has edited five volumes of the *Encyclopedia of Archaeology* (Murray 1999b, 2001) and written a single-volume history of archaeology *Milestones in Archaeology* (2007). His research on pioneers in Australian archaeology remains a seminal and much-cited work (Murray and White 1981).

Despite his reputation as theoretical archaeologist, throughout his career, Murray has committed to a range of initiatives to improve practices in archaeology, heritage, education, and research across the humanities. Handbooks on archaeological practice (Birmingham and Murray 1987), the establishment of the first indigenous training program for heritage managers, and a digital repository for historical archaeological databases in 2011 have supported the integration of archaeological outcomes for public consumption in Australian museums and school curricula.

Tim Murray built the La Trobe Archaeology Program into a global archaeology department and has fostered the research of many students and colleagues. He has successfully engaged in productive collaborations with historians, technical specialists and heritage experts, and archaeologists working in the discipline's many subfields.

Museo Chileno de Arte Precolombino, Chile

José R. Berenguer
Museo Chileno de Arte Precolombino, Santiago, Chile

Basic Information

Located on 361 Bandera St., the Chilean Museum of Pre-Columbian Art (www.precolombino.cl) preserves, investigates, exhibits, and spreads one of the best and most prestigious private collections of Pre-Columbian art of the American continent. From the initial donations made by the founder of the institution, the Chilean architect Sergio Larraín García-Moreno (1905–1999), collections have increased due to new donations, extended loans and acquisitions among other

issues. At present, the estate holds 8,500 objects, some of which are presented in two permanent exhibitions: Pre-Columbian America in Art (Aldunate et al. 1998) and Chile before Chile (Sinclaire 2014).

To visit *Pre-Columbian America in Art*, it is necessary to go to the second floor, where it can be observed a monumental metallic map of North America, Central America, the Caribbean and South America, with the main cultural areas and indigenous societies that developed before the European contact. Distributed in seven rooms, with an area of 740 m^2, there are 75 display units in which approximately 700 pre-Columbian pieces are exhibited. With a map of the American continent without the political boundaries that today divide the countries, the exhibition tries to represent the diversity of American peoples through their works of art, trying to balance an aesthetic approximation with a thematic approach, without putting aside the historical, geographical and cultural context of the objects. The starting point of the visit is an introductory room, where the pieces that the Museum estimates are its masterpieces are displayed. At the end of this room, the visitor can go to the right and visit the show cases destined to the Middle and Mesoamerican areas, or go to the left, to visit those consecrated to the Southern and Central Andean areas, and the Caribbean and Amazonian areas. Maps and pictures on the cultural area corresponding to each room provide spatial, temporal and cultural information. The itinerary includes a room dedicated to textile art, considered by many as a "Major Art of the Andes". A second itinerary, shorter and exclusively thematic, can be made circulating in the outer corridors of the rooms.

To visit the *Chile before Chile* exhibition, it is necessary to go down to the first floor of the building. The area of its only room covers 440 m^2, where 300 objects are displayed in 17 large showcases and other display units. The exhibition is divided into five geocultural regions: Far North, Near North, Central area, Southern area and Rapa Nuí (Eastern Island). Although the montage is markedly aestheticizing and the content essentially thematic, a panel of more than 4 m long provides space-time information on the societies mentioned in each expository unit. The purpose of this exhibition is to celebrate the first human societies that inhabited the territories that today constitute the Republic of Chile, to make their achievements, art and beliefs public, including these peoples'descendants, the present indigenous ethnic groups. Contents related to this exhibition can be found at www.chileantesdechile.cl.

In the first floor, corresponding to the surface level of the building, there are two rooms, with an area of 285 m^2, which are used together or separately for temporary exhibitions. In the site www.precolombino.cl many of the more than 50 temporary exhibitions made by the Museum during its more than three decades of existence can be "visited". In the book Compartiendo memoria (Berenguer and Torres 2011) curatorial and museographical foundations can be known as well as the backstage of 30 those exhibitions, as different members of the Museum's historical community remember. Temporary exhibitions for children have been set up, others focused on a single large piece of pre-Columbian art, in a unique theme or a single culture, some focused on topics usually avoided in our milieu, or in traditionally excluded groups from the national museum discourse.

The Museum is much more than a set of showrooms. An important component is the Department of Conservation, where the heritage of archaeological and ethnographic objects of the institution is registered, preserved and restored, as well as those collections in transit due to some temporary exhibition. The Curatorial Department is responsible for developing the concept, the script and the contents of the exhibitions, as well as advising visiting curators, editing publications associated with each exhibition and organizing scientific meetings. In addition, each curator develops basic research projects, particularly in archaeology, and supervises projects of associated researchers, mainly those related to the Museum's collections, to pre-Hispanic art or to art with pre-Hispanic roots. Since 1986, this department has published the Bulletin of the Chilean Museum of Pre-Columbian Art, an

indexed journal in the main international indexes of scientific publications and the only one that publishes articles on pre-Columbian art from all over the Continent (www.boletinmuseoprecolombino.cl). With the support of private institutions, the Museum has published numerous exhibition catalogs, room guides, books, magazines and other printed material, generally in Spanish and English, which have served to increase the library's patrimony through exchange with other institutions. Almost all of these publications are on the site www.precolombino.cl, and, according to the open access policy maintained by the institution in this matter, they can be downloaded freely by any user. The Library of the Museum is a unit specialized in books and magazines of archaeology, American prehistory, anthropology, pre-Columbian art and museology, which supports the different departments and units of the institution, as well as students, professionals, researchers, artists and various sectors, at national and international level, that demand the use of information resources. One of the most recent creations is the Intangible Heritage Center, a unit focused on the local culture of Chile that offers an audiovisual archive of more than 10,000 records in video, audio and photography format to the public. The center registers, preserves, investigates and spreads oral knowledge, memory, art, ritual, history and the indigenous and *mestizo* identity of Chile. The Museum's website (www.precolombino.cl), with its several hundred pages and its great amount of information, has become a global reference on pre-Columbian America. Other presences of the Museum in the network are www.lospreco lombinos.cl (for children) and www.chilepre colombino.cl.

History

The Chilean Museum of Pre-Columbian Art operates in the former Palace of the Royal Customs, one block from the *Plaza de Armas* in Santiago. The occupation of the place dates back to pre-Hispanic times, as evidenced by the excavations carried out in the courtyards of the present Museum, which have recovered archaeological materials from the Inca and immediately Pre Inca periods (Berenguer and Torres 2011: 184–185). During the first years of the Colony it was the residence of Juan de Cuevas, Corregidor of Santiago, and between the seventeenth and eighteenth centuries, there were Jesuit settlements. At the beginning of the nineteenth century, Governor Luis Muñoz de Guzmán ordered to build the Royal Customs Palace and commissioned the military engineer José María Atero to do it. He built it between 1803 and 1807 with the Italian architect Joaquín Toesca and Ricci's plan. It is a neo-classical style building with two floors and two large interior courtyards. After Independence (1810), the building houses the National Library and from 1845 to 1968 the Courts of Justice. After a fire that year, which destroyed its facilities and archives, the palace is declared Historic Monument of Chile. In 1979, the property was transferred to Santiago City Hall, which commissioned the architect Fernando Riquelme to recover the first floor of the building, intervening through the construction of a pedestrian walkway to avoid its demolition. At the end of that decade, the Larraín Echenique Family Foundation signed an agreement with Santiago City Hall, through which the Chilean Museum of Pre-Columbian Art was created. According to this agreement, the building entity delivers the former Palace of Royal Customs for the operation of the institution and an annual contribution of money to ensure its financing. The Foundation in turn provides a collection of a thousand pre-Columbian objects and an important bibliographical and documentary complement. In 1979, under the direction of the architect Jaime Burgos Frías, the reconstruction and restoration works of the north wing of the palace began and the expert museologist and Italian architect Darko Pandakovic's counselling is achieved. Pandakovic is responsible for the design and interior equipment of the restored area of the building (Berenguer and Torres 2011: 36–40). The Museum is opened on December 10, 1981 with a permanent exhibition and a catalog of the show (Anónimo 1981). Through a series of restoration works, carried out in the 1980s and 1990s, the palace is completely rebuilt and fully equipped,

with all its facilities being used by the institution (Aldunate et al. 1998: 77).

The genesis of the original collection of the Museum is found in the passion that Sergio Larraín García-Moreno (1905–1999) cultivates, from a very early age, for medieval, oriental and modern art. This passion and his taste for collecting lead him to fall in love with pre-Columbian art, finding in this artistic past of America a stimulus to form a collection of works from the main pre-European cultures of the American continent. (Aldunate et al. 1998: 69) In 1979, Larraín donates this collection to the Fundación Familia Larraín Echenique to create the Chilean Museum of Pre-Columbian Art, and 9 years later he makes a second donation (Berenguer 1988), which materialized at the end of the following decade, after his death. One of the main features of this collection is that its pieces were not chosen for scientific or anthropological reasons, neither encyclopedic reasons, but according to the eminently esthetic criterion of the donor. From there the name "museum of art" derives, to distinguish it from one of anthropology, archaeology or ethnography (Aldunate et al. 1998: 72). However, at the time of forming the Museum's staff, it is integrated mainly by archaeologists. As a consequence, almost from the outset, a contradiction arises between the primarily aesthetic vision with which the institution is founded and the anthropological vision in which archaeologists are usually trained in Chile (Berenguer and Torres 2011: 34–35, 47–48, 51). Given this characteristic and the fact that the initial team lacked training and experience in museology, the Museum is developed with a very particular professional mark, which cannot be ignored when considering the uniqueness of its cultural offer.

The most recent remodelling of the building was carried out by the architect Smiljan Radic and concluded in 2014. He understood the redesign of the north and south patios of the building, the installation of a cafeteria, a shop and a new reception. He also understood the construction of the great hall for the permanent exhibition *Chile before Chile*, located in the underground and whose museographic project was commissioned to the British designer Geoffrey Pickup. Radic's remodelling included the construction of spacious underground facilities for the Collections Department and the Library, and the building's second floor for the offices of the Curatorial Department and the Education / Mediation and Communications and Public areas.

Major Impact

During the last 30 years and especially since the return of democracy (1990) and the enactment of Indigenous Law No. 19,253 (1993), Chile has significantly increased the interest and appreciation for the vernacular cultures of the American continent. The Chilean Museum of Pre-Columbian Art has played an important role in this change of way of thinking. A museum dedicated to art, focused on the pre-Columbian, Americanist and without frontiers, came to fill an evident void, since there was nothing similar in Chile, or in Latin America. The message of the inaugural exhibition, at the end of 1981, was that the countries of America have a common past in the indigenous peoples' history and art. Making this past known was important for a society like Chile, educated in the idea of the cultural homogeneity of the nation, to recognize its indigeneous roots, that is, its own ethnodiversity.

From this first permanent exhibition, carried out within a historical-cultural theoretical perspective, over the years, thematically structured exhibitions were transposed, partly due to the influence of the temporary exhibitions, but above all, because they allowed diverse topics to be approached in a more attractive way and without the linearity of chronologically structured expositions. *Pre-Columbian America in Art* (1998) is an example of that change of vision applied to the permanent exhibition.

Although the Museum originated in the appreciation of the aesthetic values of the pre-Columbian world, it has always been a place where principles, values and postures were confronted and questioned. The internal conflict for more than two decades between a conception of art as something purely aesthetic or contemplative and the anthropological approach to its contents, was solved as the Cultural Studies in the world overturned the old paradigm of the

autonomy of art, to install this within history and society. Although the aesthetic considerations on the exhibited pieces are important and from a Western perspective it is possible to evaluate these pieces as works of art, it cannot be forgotten that almost all are ritual objects. Today the Museum understands that just as there is gratification in contemplating the beauty of these objects, so there is in understanding its historical, functional and symbolic contents.

Among the most pressing challenges for the Museum over these years, one will be to address the legitimate concern of the sponsors for measuring the impact of the initiatives they support through the number of visitors. The difficulty is to do so without giving too much to the so-called fallacy of numerical approval and without falling into the formula of the museum-spectacle. Another challenge is to readjust the offer to a more educated, demanding, participatory and commited audience to the value of cultural diversity. This is somehow the result of the Museum's own success. To satisfy it, however, it will be necessary to move towards new discourses, formats and ways of looking, perhaps towards plural narratives and alternative visions. In particular, the Museum should advance towards proposals that use the past to reflect on the present, fostering a form of linkage between object, interpretive and public content that some call contemporaneity of meaning.

Museo de La Plata

Mariano Bonomo
CONICET-División Arqueología, Facultad de Ciencias Naturales y Museo, Universidad Nacional de La Plata, La Plata, Argentina

Basic Information

The Museo de La Plata (La Plata Museum) (Fig. 1) belongs to the Facultad de Ciencias Naturales y Museo (School of Natural Sciences and Museum) of Universidad Nacional de La Plata (La Plata National University), Argentina. It was founded in 1884 as a museum of Buenos Aires Province dedicated to research and the display of Natural History, Archaeology, and Fine Arts, among other disciplines. In 1906 it became part of the public university. Since then it has played a key role at national level in academic training in Anthropology in close proximity to the Natural Sciences, a field that has been the main focus of the institution since the early 1920s (García 2010). It is currently an important center for paleontological, zoological, botanical, and geological research and for studies of the different anthropological fields organized within the Anthropology, Ethnography, and Archaeology Divisions. Since its inception, the museum has significantly contributed to education through its exhibits, three of them dedicated to the Archaeology of Argentina, Latin America, and Egypt. The museum's magnificent neoclassic building were designed by the Swedish Henrik Gustav Adam Aberg and the German Carl Ludwig Wilhelm Heynemann. The building was inspired by the European museums of the time, but it had a delicate Americanist influence on its decoration, with designs depicted on textiles, metal objects, and pottery of Aztec, Maya, Andean, and Mapuche origins.

Major Impact

Archaeology, which in Argentina became a research field in the second half of the nineteenth century, was one of the pillars of the Museo de La

Museo de La Plata, Fig. 1 La Plata Museum. (Photo by Bruno Pianzola)

Plata. The museum's foundational collection comprised mainly of anthropological and archaeological objects donated by its founder, the collector of antiquities Francisco P. Moreno (Farro 2009; Podgorny 2009). Moreno appointed the naturalist Florentino Ameghino for a short period as the museum's deputy director and secretary, who later proposed the existence of a local hominization process, arguing that humankind had originated in the Argentinean Pampas during the Tertiary period. Moreno also involved the institution in the border dispute with Chile, organizing topographic expeditions along the Andes. Samuel Lafone Quevedo and Luis María Torres, who dedicated much of their lives to Archaeology in Argentina, succeeded Moreno as directors of the museum. In this context, the discipline was an essential element on which the foundations of the institution were laid in its first 50 years of existence. This led to scientific expeditions for the collection of archaeological objects on the field and to the acquisition of important collections, such as that of Benjamín Muniz Barreto, consisting of a unique documentary and photographic record and more than 10,000 items obtained in excavations in the Northwest of Argentina. These objects are part of the extensive collections of the Archaeology Division, which now comprise over 90,000 items mainly from Argentina but also from other American, European, African, and Asian countries. It is therefore the most important repository of archaeological remains in Argentina.

Besides managing and conserving the collections, the Archaeology Division is responsible for coordinating archaeological research studies developed in the Museo de La Plata. It is one of the museum's divisions with the largest number of members; currently more than 60 among researchers, fellows, technicians, and curators of the collections of its three deposits. In addition to the different subjects studied about human behavior through material culture, a constant interaction with Earth and Biological Sciences takes place at the institution with a strong naturalist imprint. These investigations are carried out in order to enhance the cultural heritage of past societies, within an updated scientific framework guided by the ethics

of professional practice and respect for the rights of indigenous people.

Most of the archaeologists that work at the museum take part in the academic education of undergraduate and graduate students of the Facultad de Ciencias Naturales y Museo of Universidad Nacional de La Plata. They are professors in the Doctorate in Natural Sciences, created in 1912 as an undergraduate and a doctorate program, and professors in the undergraduate Anthropology program, created in 1958, which includes three specializations: Social Anthropology, Physical Anthropology, and Archaeology. At the same time, the Anthropology program was created at the University of Buenos Aires (UBA) as well as the National Council of Scientific and Technical Research (CONICET). Following the French CNRS, this last institution aimed to train scientists dedicated exclusively to research. This promoted Archaeology as a discipline in the following decades and continues to do so.

College life at the museum was severely affected by successive interventions, termination of teaching positions, and serious institutional problems on several occasions (e.g., 1946, 1966, 1973, and 1976). A period that was particularly painful was the last military dictatorship (1976–1983) marked by a strong control of the subjects' social contents; the Social Anthropology Specialization was temporally closed, some faculty members such as Alberto Rex González were laid off (see Soprano 2010; Politis and Curtoni 2011), and some researchers were ousted from the museum, and consequently their research teams were dismantled. During this fateful period of Argentinean history, a significant number of students and, to a lesser extent, young graduates of Anthropology between the ages of 20 and 30 were persecuted due to their political activism and left-wing ideas and were kidnapped and disappeared or murdered by the military dictatorship. Only after the return of democracy in 1983 was academic freedom and individual rights reestablished, thus giving rise to a new period for teaching and researching Archaeology at the Museo de La Plata and in Argentina.

Since 1994 the return of the indigenous chief Inakayal's remains was made to his Tehuelche descendants in the Patagonia homeland, becoming the first reburial held in the country. After the military campaigns (1879–1880) against the Pampas and Patagonia indigenous peoples, Inakayal was transferred from prison to the Museo de La Plata, where he and other indigenous people began to do maintenance tasks and served as live models for mural paintings. When Inakayal died, his brain, scalp, bones, and mortuary mask were extracted. All these elements became part of the museum's collections as cultural heritage of the past. Finally, in 2006 upon the request of indigenous communities, the aboriginal human remains were removed from the museum's exhibitions. Thus, a complex but essential path toward reparation for the rights of indigenous societies has begun, enabling them to decide on the fate of their ancestors' remains. In this way the Museo de La Plata has taken an active role in the restitution of human remains in Argentina.

The Museo Etnográfico "Juan B. Ambrosetti"

Mónica Alejandra Berón
IDECU, UBA, Buenos Aires, Argentina

The Museo Etnográfico "Juan B. Ambrosetti" was founded by the Facultad de Filosofía y Letras of the University of Buenos Aires in 1904 with the purpose of systematically developing anthropological and archaeological research, as well as to establishing the social and humanistic disciplines in Argentina. Its founder was Juan Bautista Ambrosetti, who directed the institution between 1904 and 1917. He imagined it as a public space for the transfer of knowledge and education in the broadest sense, as well as a research and higher education institute (Perez Gollán 1997 [1987]). At that time, the museum was one of the first university institutions in South America seriously concerned about archaeological research, along with La Plata Museum and the university itself. The broad research role of the museum required the constitution of collections that were capable of covering geographies and cultures of the five continents. In addition, a primary specialization in Argentine archeology and ethnography was developed. The establishment of this coincided with the creation of ethnographic museums in different parts of the world in the late nineteenth and early twentieth centuries, establishing an institutional network for the exchange of publications, materials, and information.

The museum's collections were developed thanks to donations, purchases from merchants of cultural goods, and the financing of expeditions of their museum personnel and scientists linked to them. Between 1904 and 1912, the number of donations reached the approximate number of 2000 objects, from some seventy-five donors. These were added to the materials and information obtained through archaeological and ethnographic campaigns, which, all together, managed to compose a heritage of 12,156 cataloged pieces (Ambrosetti 1912). The establishment of the museum involved the formation of networks of collaborators, which ranged from patrons and officials to collectors, military, and businessmen. Ambrosetti planned, as a diagrammed, as a strategy, the laying of the development of a network to support the local collection of objects, using administrative and bureaucratic state channels (Ambrosetti 1912; Perazzi 2011; Pegoraro 2005). The collection was also increased through purchases of private collections and exchanges, based on international communication networks that relied on diplomatic connections, and ordering originals, replicas, decals, or three-dimensional reproductions from related institutions (American Museum of Natural History of New York, Royal Ethnographic Museum of Leyden, Smithsonian Institution of Washington, National Museum of Fine Arts, among others). However, perhaps the most important aspect of the museum was the organization of field work, related to the role of Ambrosetti as a teacher of American Archeology, which gave students the possibility to learn the methods and techniques of field work and also cooperate in the laboratory tasks that were undertaken in the Museum. There were 24 expeditions between 1904 and 1929, as well as the Debenedetti (1915) and the Holmberg (1924) Expeditions, all focused on the archeology of northwestern Argentina. Equally, instructions were also sent to collect archaeological and ethnographic objects in different areas of Patagonia (Pegoraro 2005).

At the beginning the Museum worked in the basement of Viamonte 430 Street, where Buenos Aires University had a location. Then, in 1927 it was moved to its current headquarters of Moreno 350 Street, in the neighborhood of Monserrat, a building designed by Pedro Benoit, a famous architect, as the first seat of the Faculty of Law

at the university. In 1947, almost all the anthropological materials that were part of the National Museum of Natural Sciences were incorporated (except some of Ameghino's collections), accreting notoriously the patrimonial heritage of the Ethnographic Museum. The creation of the Anthropological Sciences Career in 1958 was a fundamental milestone in the development of this institution, beyond socio-political developments that would affect the growth of Argentine Anthropology at different times (i.e., the Night of the Long Sticks during the penultimate military dictatorship,1966–1973; and the last civic-military dictatorship, 1976–1983).

Thus, began a trajectory that characterizes and particularizes the Museo Etnográfico, even today, which links teaching, research, documentation, conservation, transfer, educational outreach, and commitment to the community, each intimately associated with the other in a single institution and embedded in an institution of high academic studies.

However, it when J. A. Perez Gollán was Director (1987–2005), that innovative and modern proposals and management plans were prepared. While these are recorded in various documents, they, which only partially reveal the major intellectual, ideological, and empirical changes that took place since then (Perez Gollán 1997 [1987]); Pérez Gollán and Dujovne 1996, 2001). During this period, weaknesses vacancy areas, and needs were diagnosed, both human and material. He underpinned a reopening of the exhibitions, both to scholar and general public http://museo.filo.uba.ar/exposiciones Exhibitions and http://museo.filo.uba.ar/actividades activities give an account of the state of the matter in the topics they address.

Currently, the Museum's exhibitions focus on historical and social processes and are complemented by other activities (http://museoetnografico.filo.uba.ar). The preparation of exhibitions draws on the skills of researchers, designers, curators, and educators. The available exhibition space is limited and therefore most of the collections are stored. Researchers and students can access the collections stowed in the deposits. For the transfer of knowledge, there are two specialized areas: an Educational Outreach Area, which works with different levels of education and with teacher training institutions; and a Cultural Action Area that deals with the general public as well as cultural and artistic activities related with the mission of the Museum.

The research also focusses on conservation activities. Good documentation is essential for the conservation and management of collections and is inextricably associated with the investigation of the meaning of cultural materials. The documentation and research of objects turn them into heritage that can be passed on to future generations. The tradition of teaching was part of the establishment of the museum. Even today, there are lectures and seminars by anthropology staff of the Facultad de Filosofía y Letras of the University of Buenos Aires, as well as a specialization in Museums, Cultural Transmission and Anthropological Collections Management. The Museo Etnográfico develops workshops on museological issues, and teacher training courses, in addition to training its own staff and those from other institutions. For over 100 years, the Museo Etnográfico "Juan B. Ambrosetti" has played a lead role in conserving, researching and teaching of ethnographic collections in Argentina.

Museo Nacional de Antropología, México

Isabel Medina-González
Escuela Nacional de Conservación, Restauración y Museografía, Instituto Nacional de Antropología e Historia (INAH), Mexico City, Mexico

Basic Information

The Museo Nacional de Antropología (the National Museum of Anthropology, http://www.mna.inah.gob.mx), hereafter MNA, is the oldest, largest, and most famous anthropological museum in Latin America. Located in Chapultepec Park in Mexico City, the MNA focuses on displaying the cultural diversity and development of native societies of Mesoamerica through an exhibition that begins by explaining the meaning and practice of anthropology. It then addresses the origins of the American indigenous peoples (including the theories of Paleo-Indian migration and settlement in the Americas) and goes on to explain in a rather "monographic" fashion, the characteristics and achievements of the principal pre-Columbian ancient civilizations from the pre-Classic, Classic, and post-Classic periods (i.e., Olmec, Teotihuacan, Toltec, Mexica-Aztec, Maya, Mixtec-Zapotec, and Occident and Northern cultures). The exhibition culminates in an ethnographic exhibition on various indigenous communities currently living in Mexico. This perspective, broad in both time and space, represents the core spirit of the Latin American School of Anthropology to study and disseminate American indigenous cultures, which is also articulated in the museological and architectural rationale of the MNA, as well as in its research, dissemination, and educational activities. Since 1939, foundation year of Instituto Nacional de Antropología e Historia (INAH, today part of the newly established Mexican Ministry of Culture), the MNA has been one of its most prominent (national) museums.

History

The genesis of the MNA's archaeological collection can be traced back to the scientific cabinets of collections accumulated in New Spain and, in particular, to the late eighteenth-century collection preserved at the Real y Pontificia Universidad de México (1551–1865), an early academic and higher-educational institution, where – inspired by a Creole nationalistic ideology – the first Museo Nacional Mexicano (Mexican National Museum, MNM) was officially founded by the government of the newly independent Mexican Republic in 1825 (Morales Moreno 1994: 164, 172). Although Mexican archaeology was a subject of burgeoning interest for both local and foreign scholars during the first half of the nineteenth century, local political instability surely limited the academic and curatorial development of the MNM until 1865, when it was relocated to the former Casa de Moneda, a northern annex of the Palacio Nacional (Solis 2001: 34).

The following three decades saw the consolidation of the MNM with the opening of a series of themed galleries (like the famous Galeria de Monolitos), that displayed documents, natural history specimens, antiquities, and historical artifacts, the establishment of a library devoted to both public instruction and scholarly research, the publication of scholarly journals (*Anales del Museo* y *Revista Científica Mexicana)*, and the launching of a series of courses and academic events on national history, archaeology, ethnology, and indigenous languages that can be considered the disciplinary origins of anthropology in Latin America (Morales-Moreno 1994: 238–304).

With the departure of the natural history collections to the Museo del Chopo in 1906, the

MNM reformulated its *reason d'être* according to its newly acquired name: Museo Nacional de Arqueología, Historia y Etnografía (the National Museum of Archaeology, History and Ethnography, hereafter MNAHE), a process that initiated a flourishing era with growing responsibilities. Apart from the accession of a large number of antique sculptures and artifacts from all over the country acquired from private collections and field expeditions organized, authorized, or supported by the museum itself, aid from the federal government enabled the renovation of the exhibition galleries that became not only the depositary of national treasures but also the showcases for the visualization of an imaginary golden pre-Columbian time that provided ideological foundations for the Porfiriato regime from a scholarly perspective (Morales-Moreno 1994: 305–83).

By 1910, the narrative of this political agenda that reconciled patriotic visions of ancient and modern Mexico was articulated by the museum hosting the celebrations of the 100th anniversary of the Independence of Mexico. Then the MNAHE also evolved into a complex multifaceted institution that consisted of departments of archaeology, anthropology, history, ethnography, anthropometry, industrial art, conservation of archaeological and historical monuments, publications, and education. Furthermore, within the framework of the XVI International Congress of Americanists, American Anthropology experienced a key event in its professional evolution with the founding of the International School of Archaeology and Ethnology within the MNAHE, the predecessor of the ENAH-INAH (Rutsch 2007).

Although the Mexican Revolution brought about the interruption of the museum's activities for period of time, post-revolutionary governments later ensured that the MNAHE maintained its long-standing position as the "national institute *par excellence*, that unlike any other, reflected the very patriotic essence" of Mexico (Castillo Ledón 1924, in Morales Moreno 1994). Further acknowledgment of the museum's educational role was confirmed by its incorporation into the Secretaría de Educación Pública (the Public Education Ministry) in 1921. During the 1930s, ethnographic research by the MNAHE was central to the articulation of an indigenous policy articulated by the regime of President Cardenas as well as to the development of *avant-garde* anthropological studies, congresses, and exhibitions (Solis 2001: 35).

After the establishment of Instituto Nacional de Antropología e Historia (the National Institute of Anthropology and History) in 1939 and the foundation of the Museo Nacional de Historia (the National Museum of History) in 1944, the MNAHE underwent its last organizational transformation becoming the Museo Nacional de Antropología (MNA), a museological, research, and scholarly institution with a solid and growing international reputation.

In 1964, with the full support of President López Mateos, a new building for the MNA was inaugurated at Chapultepec Park, Mexico City (Fig. 1). Its architectural design, by Pedro Ramírez Vázquez (1919–2013) (2008), represented a revolutionary concept, with a total area of 70,000 m^2 with 30,000 m^2 for galleries and open spaces for exhibition purposes and 15,000 m^2 for collection deposits, curatorial, research, and service sectors.

Impact

Apart from being a major touristic and educational landmark in Mexico, the MNA is an icon of Mexican museography worldwide. Its galleries are organized around an open central patio, decorated with the famous "parasol" – a monumental roofed pillar with engraved decoration inspired by pre-Colombian figures – and an internal garden water mirror, which provides independent access to exhibitions and thus free visitor movement and permits the integration of the museum with Chapultepec Park. Specifically designed decorative architectural elements and a series of commissioned works of art by famous modern Mexican artists (Rufino Tamayo, Carlos Mérica, Rina Lazo, Mathias Goeritz) complement the exhibition setting, which includes replicas of pre-Columbian buildings and lifelike reconstructions

Museo Nacional de Antropología, México, Fig. 1 Facade of Museo Nacional de Antropologia (MNA-INAH). (Credits: Mtra. Martha Elena Ortiz Sánchez)

of some aspects of indigenous cultures (Ramírez Vazquez 2008).

The MNA houses the National Anthropological Library, which holds the most important and largest collection of pre-Columbian codices in the world. It additionally has three large auditoriums for academic events; galleries for temporary exhibitions, recently presenting displays on ancient world civilizations; open spaces, used for academic and more recently political ceremonies; administrative, research, and laboratory areas; offices for educational services and guided tours; parking lots; shops; a restaurant; and a cloakroom.

The order of the archaeological galleries, defined by a cultural-historical theoretical approach, as well as the prominent position of the Aztec culture in the arrangement, has been subject to several critiques, including one by Octavio Paz (1970: 279–281), who exposed the political agenda implicit in the representation of Mesoamerican cultures, stating that the MNA is a architecturally crafted myth that represented the currency of an ideological nationalistic model based on the political domination of the central Mexican political aristocracy and thus questioned the idea that Mexicans are still articulating its patriotic archetype on the basis of admiring pre-Columbian ruins. Further criticism regarding the political bias that uncovers the ethnographic displays has also been addressed (i.e., Carillo Sierra 1994: 48).

Since its inauguration, the MNA has undergone few changes in its original architecture and museography, although from 1998 to 2005, some galleries, including the Temporary Exhibition Area, were renovated as part of a major restructuring plan, a work that was concluded before 2005, when the museum celebrated its 40th anniversary (Ramírez Vázquez 2008). Since then, the MNA has hosted major blockbuster exhibitions on various ancient civilizations, thus underlying the international impact of both the museum and INAH. During 2014, the MNA patronage celebrated the 50th anniversary of the museum with a series of events, including the publication of a lavished illustrated book (A.A.V.V 2014) composed of essays by prominent Mexican historians, archaeologists, and art specialists, such as Eduardo Matos Moctezuma, Salvador Rueda, Colette Almanza, Frida Gorbach, Thalía Montes, Antonio Saborit, Ana Garduño, Frida Escobedo, and Claudia Barragán, who analyzed its origins and history. This *obvre* that saw light into both a commercial (5000 items) and a collector's edition (250 items).

Museo Nacional de Arqueología, Antropología e Historia del Perú

Carmen Arellano Hoffmann
Museo Nacional de Arqueología, Antropología e Historia del Perú, Ministry of Culture, Lima, Peru

Basic Information

Founded in 1822, the National Museum – as it was formerly known – is Peru's oldest state museum. With more than 23,000 m^2, 30 exhibition galleries, 100 employees, and about 250,000 objects, it is also the largest and most prestigious of the country. Originally created as a History, Archaeology, Ethnology, and Natural History Museum, it was in the first half of the twentieth century that it split into an Archaeology-Anthropological Museum and a History Museum, although sharing a common building since 1924. The Natural History section was also separately refounded in another museum and building. In 1992, the Museum was reunited but keeping the official names while it was divided into National Museum of Archaeology, Anthropology, and History of Peru.

Its importance lies in the vast and diverse holdings, which are more than 250,000 items of invaluable ceramics; textiles; metals; lithic, organic, human, and animal remains; Colonial and Republican paintings; and other artwork, dating from the beginning of Andean culture c. 5000 BCE to the present. The archaeological collections are world renowned because most of them have archaeological context and are well documented. The museum houses a historical archive as well as a photographic archive and library that are accessible to researchers and students.

Its permanent exhibition halls display its achievements, which is the Peruvian civilization development in a chronological sequence spanning from the first settlers to the Republican period. Signature objects are the Raimondi stela; the largest known Nasca drum (almost 1 m high) (200 BCE–600 CE); a high relief sculpture depicting crossed arms of Kotosh (2000 BCE), over 200 large textiles, called mantos, of Paracas culture (500–100 BCE), the oldest ones in the Americas; a significant collection of Colonial paintings from the Cuzco School; and a large-scale model of Machu Picchu with buttons that allow visitors to identify key sectors of the complex.

The building itself is also attractive for its architecture and interior gardens. Built by renowned Portuguese architect Raul Maria Pereira, it was the first design for a museum in Peru. The building was constructed around a Colonial house that dates probably to the seventeenth century. The Spanish Viceroy Jose de la Pezuela bought the house in the late eighteenth century as his summer residence. During the Independence, the Libertadores Jose de San

Martin and Simon Bolivar lived here. Hence, the house is known today as the Quinta of the Libertadores. It shows the former inhabited spaces of Don Jose de San Martin and Don Simon Bolivar.

The National Museum is located in Pueblo Libre, a district about 3 km from downtown Lima.

Major Impact

The Museum is paramount to the history of Peru. After more than 180 years, the National Museum has played a main role in defining Peruvian history and identity. From its beginning, the directors strived to study and reconstruct the past events of Peruvian history, since nothing beyond the Inca period was known. The museum's first collections gathered in the nineteenth century were lost to Chile during the Pacific War (1879–1884). Besides the Colonial paintings and other historical objects that were timely put in safety hands, the only archaeological item recovered was symbolically the Raimondi stela, which depicts the ancient Andean Viracocha deity dated c. 1000 BCE. This deity accompanied the cultural development of Peru until the Inca period. It is a famous stone carving of the Chavin culture found by the Italian explorer Antonio Raimondi in 1861. From 1906 onward, the new museum's directors started a series of field researches in Archaeology and Ethnology, collecting material that was the foundation for the reconstruction of Peruvian past as it is known today. Especially the study of the pre-Hispanic history based on extensively archaeological excavations was the main focus of the National Museum. This task is nowadays no more performed, and the museum activities are those dedicated to exhibits, education, and other outreach cultural activities.

The museum's collections are formed not only by whole pieces but also include over 10,000 boxes with archaeological remains as products of several excavation campaigns. Other research material that is invaluable for scientific study can also be found. Along with the material, the archive holds archaeological field notes, photographs, drawings, and other historical documentation.

Museo Nacional de los Ferrocarriles Mexicanos

R. B. Brown
Museo de la Revolución en la Frontera, Centro INAH Chihuahua, Chihuahua, Mexico

Basic Information

Opened to the public on May 5, 1988, the Mexican National Railroad Museum, *Museo Nacional de los Ferrocarriles Mexicanos* (MNFM), is located in two old railway stations: *Ferrocarril Mexicano* and the *Mexicano del Sur* in Puebla, Puebla. Public access is through Calle 11 Norte, 1005, Centro Histórico, Puebla, Puebla. The principal phone number is (+) 222 774 0106, and the web address is http://museoferrocarrilesmexicanos.gob.mx/. It also has a presence on Facebook, Twitter, and YouTube. It receives about 100,000 visitors each year. Most days it is open from 9AM to 5PM.

The outdoor exhibit covers the grounds and marshaling yards of both stations and is composed of an extensive collection of rolling stock from the late nineteenth to the mid-twentieth century. The collection includes engines (locomotives), carriages (coaches), brake vans (cabooses), flat wagons (flatcars), covered goods wagons (boxcars), and dedicated and specialized wagons such as cranes, mail cars, and so forth. Many are open to inspection.

The oldest locomotive is FCM 40 which was built by Baldwin Locomotive Works, Philadelphia, USA, in 1881. It entered service as a wood burner and was subsequently updated to first a coal and then oil burner. It is a 2-8-0 with a standard gauge of 4 ft and 8.5 in.

The youngest locomotive is the Diesel Electric SBC – 22003 which was built by the Electro-Motive Division of General Motors in 1944. It entered service on the Sonora-Baja California Railroad in 1964 and heralded the change from steam to diesel-electric power in Mexico. It is the last known FT model in existence and in serviceable condition.

As of January 2012, the MNFM includes the Railroad Center for Documentation and Research: *Centro de Documentación e Investigación Ferroviarias* (*CEDIF*) which houses an extensive collection of original documents, plans, and photos as well as a full research library that deal with all aspects of the construction, development, and maintenance of the principal railroads and many subsidiary lines that are generally available to researchers weekdays from 9AM to 5PM. Appointments are advised.

The library of the *CEDIF* houses over 40,000 documents ranging from the project of the earliest proposed railroad from the port of Veracruz to Mexico City, which was printed by Ignacio Cumplido in 1837, to many modern academic publications. It is complemented by a Historical Archive, Special Collection of Plans, Photographic Archive, and the Jésus García Oral History Archive.

The Historical Archive includes about 4 km of files and documents that principally deal with the administration of the *Ferrocarril Mexicano* (1869–1950), *Ferrocarril Sudpacífco de México* (1887–1960), as well the *Junta Directiva* of the *Ferrocarriles Nacionales de México*. The Special Collection of Plans houses over 200,000 plans dating as far back as the Imperial Mexican Railroad of the 1860s. It also includes the architectural plans for many stations and plans that complement the different inventories undertaken in the twentieth century. The Photographic Archive includes some 86,000 images. Some 31,500 are products of a national inventory undertaken in the 1920s and 1930s. The Jésus García Oral History Archive includes over 100 recordings of active and retired railroad personnel as well as riders of the "Bestia," the freight train that transports illegal immigrants from Central America to the southern United States border.

Since its founding, the *MNFM* has supported and organized 14 Nation Meetings of Railroad Researchers (*Encuentros Nacional de Investigadores del Ferrocarril*) which have taken place in Puebla, Puebla; San Luis Potosí, San Luis Potosí; and Xalapa, Veracruz.

Since 2007, the *MNFM* has published the journal *Mirada Ferroviaria* three times a year, available

online (http://www.museoferrocarrilesmexicanos.mx/boletines.php).

Major Impact

The indoor exhibit relies on graphics and railway paraphernalia to portray the economic and political importance of the Mexican railway system. From its humble beginnings in 1837, the railway played a crucial role in the economic expansion in the nineteenth century that culminated in the Mexican Revolution (1910–1918). During the Mexican Revolution, control of the railway lines had both strategic and tactical implications. After the Mexican Revolution, most of the railway infrastructure was either replaced or updated. It reached its apex in the mid-1940s, but the expansion of the national road system and the associated intercity (interurban) bus systems and trucking companies, together with a falling rate of reinvestment, led to stagnation and then decay.

Museo Tecnológico del Vidrio

Paloma Pastor Rey de Viñas
Museo Tecnológico del Vidrio, Real Fábrica de Cristales, La Granja de San Ildefonso, Segovia, Spain

Basic Information

The Museo Tecnológico del Vidrio (Technological Glass Museum) is located in the old La Granja Royal Glass Factory, one of the most significant industrial building of the Enlightened Spain (Fig. 1).

In this sober building, built by order of King Charles III according to the plans of the quantity surveyor Joseph Díaz Gamones, the National Central Glass Foundation was set up in 1982, with the goal of reclaiming the old building, its history, and its most traditional techniques. Its over 25,000 m^2 of area currently houses the Technological Glass Museum, the Library, and the

Museo Tecnológico del Vidrio, Fig. 1 Part of the building of the Royal Glass Factory of La Granja

Higher Education Institution of Glass, as well as Furnaces and workshops.

For further information, go to http://www.fcnv.es/.

Major Impact

The visit begins in the Furnaces Hall, an outstanding space with a basilican design, having two great domes made of brick, where the melting furnaces are located. In this singular space, visitors find the Technological Exhibition, where you can learn about different manufacturing processes of glass, from the traditional to the mechanized by means of diverse elements such as furnaces from distinct eras, machines and ancient mills, work tools, molds, and raw materials.

From the firewood patio visitors can access to the glass furnace, where the glassblowers reproduce the ancient pieces of La Granja crystal with great skill using the traditional glassblowing method with a blowpipe. Undoubtedly, this is the favorite space for our visitors, where the magic of glass is shown in its entire splendor. Nowadays, Royal Glass Factory production are faithful to its handmade tradition and its superior quality of raw materials (Fig. 2).

On the other side of the Furnace-Hall, you can find the Stainedglass room, with an important collection from the workshops of Maumejean. Towards the end of the nineteenth century and in the first half of the twentieth century, this prestigious workshop, with commercial offices in France and Spain, supplied a great number of religious and civil buildings, and individual homes, in Europe as well as America, Africa, and even Asia. The stainedglass window of Cristo de Martorell, exhibited in the 1925 World Fair of Paris, heads the exhibition from the large Southern window of the second dome.

Crossing the Museum lounge, we come into the Polishing Nave, a wide space of rectangular design, with a narrow corridor in the center, supported by two rows of pillars and lowered arches, all made of granite. In this nave, you can still see the remains of the famous Water Machine, designed by Demetrio Crow, which moved not only the grinding benches, used to polish the glass of mirrors, but also the various mills for grinding raw materials, including several lathes to work the windows of the upper floor. A scale model in the gallery explains the peculiarities of this hydraulic machine.

In this great nave, the visitor can also find the Gallery of Bottles and Containers which gathers

Museo Tecnológico del Vidrio, Fig. 2 Furnaces-Hall of the technological area of the museum with machinery used in glass production

in one place the best European collections of bottles, flasks, and containers for pharmaceutical products, as well as for storage of solids and perfume bottles, organized chronologically from the sixteenth to the nineteenth centuries. You can also find how the English wine bottle evolved through the centuries, as well as other peculiarities of this interesting collection.

Through the Polishing Nave, the visitor can access to the historical production of the Royal Glass Factory Gallery, composed of one of the most important collections nowadays, not only for the number and diversity of its pieces but also for their high quality and originality. This collection was formed by pieces from different loans, such as of the National Museum of Decorative Arts of Madrid, Patrimonio Nacional, and the Prado Museum, as well as its own collections, acquired over the years by the National Central Glass Foundation.

Finally, on the upper floor of the same nave, the visitor finds the Gallery of Contemporary Glass Exhibition, which includes the most recents glass trenes of the las few years all over the world. Of note is the collection of sculptures by the Segovian Torres Esteban, as well as collections from Japanese sculptors and from the Czech Republic.

Museos de Real de Monte

Belem Oviedo Gámez
AHMM, TICCIH México, Centro Pachuc de Soto, Hidalgo, Mexico

Basic Information

The Historical Archives and Mining Museum is a Civil Association located in the mining district of Real del Monte and Pachuca, in Central Mexico. It is dedicated to the protection, conservation, and reusing of industrial heritage sites since 1987. It mainly consists of historical archives and several museums.

Major Impact

The Historical Archives of the Compañía Real del Monte y Pachuca (AHMM) houses a collection dating from 1727 to 2002. The AHMM opened in April, 1987, are among the most important of their kind in Mexico. Being one of the few private archives with a general guide to its holdings published, it has acquired the status of a legal entity. Its collection of textual and visual documents has been the cornerstone for the establishment of four museums and is mostly grounded upon a clear feedback system between the archive and the museums (e.g., Oviedo Gámez and Hernández Badillo 2003). Since the opening of these facilities, the demand for service has increased not only the archive but the periodicals and newspaper archive as well as the library. Today, a historical archive with 275 years of information, mostly as the result of the concentration of archives, has been enriched by an image bank of photos, plans, and posters, fully available for scholarly research, to students, and the general public.

Opening in July 1993, the Mining Museum is devoted to the history of geological explorations, exploitation, and mineral processing. It also features social and labor aspects, such as the organization of workers and the efforts on the part of

Museos de Real de Monte, Fig. 1 Acosta Mine Site Museum. (Photographed by Marco A. Hernández Badillo)

Mexican, British, and American entrepreneurs and workers to reduce the number of mining accidents. Located in the main patio and gardens is The industrial archaeology space. There one can see not only the heavy machinery employed at that time but an old perforator from the late nineteenth century. Also on display are the Mack vehicles that transported the ore from the processing hacienda of Loreto to the railway station, and an 80-t crane from "The Brown Hoisting Machinery Co." of Cleveland.

The Acosta Mine Site Museum (Fig. 1) opened in July, 2001, and includes the following areas: the superintendent's office and house, a head frame, and the drain gallery used to extract minerals. In addition, two of the major attractions for the visitor are the drain gallery, used to extract minerals, and the entrance tunnel to the depot with a level of 180 in the "Mina Dificultad." In addition, there is The Forge and The Boiler Room, where archaeological excavations exposed the nineteenth century steam boilers' ash pits. Of the former, two of them were restored and one more was consolidated in order for the public to see the condition in which they were. The material collected consisted of iron and ceramic pieces and brick crumbs. Finally, there are two areas specially designed for children in which the first history and visual arts workshops have taken place. These events culminated in the publication of a guide on the Acosta Mine Site Museum illustrated by children.

The "Nicolás Zavala" Cultural Center/Workers' Medicine Museum opened in October, 2004. The Hospital of the Compañía Real del Monte y Pachuca (CRDMyP) consists of preserved twentieth century buildings, furnishing, surgical and rehabilitation equipment, and x-ray machine and an apothecary that was donated to the AHMM in 1996 by the CRDMyP. When it ceased to function, the following areas and services were present: a reception area, an apothecary, an x-ray room, and a room for hospitalized patients. Besides this, there was a doctor's office, a nurses' station, and recovery, treatment, and rehabilitation rooms. Finally, it included an operating room with its sterilization and equipment area, a bathroom with shower and tub, an area for ironing sheets, and a mortuary chapel. All of these facilities and features as well as a laundry room are housed in the Workers' Medicine Museum (Fig. 2).

The exhibition display design respected this division so that a visit to the museum begins with a stop at the former chapel. There one can see posters printed by the safety department

Museos de Real de Monte, Fig. 2 Workers' Medicine Museum. (Photographed by Marco A. Hernández Badillo)

Museos de Real de Monte, Fig. 3 La Dificultad Mine Site Museum. (Photographed by Marco A. Hernández Badillo)

describing accidents that occurred in mines. It includes the Archives of the Word.

The Dificultad Mine, Site Museum and Interpretation Center, was opened in May, 2011. The main objective of the museum is to offer to the visitors a comprehensive vision regarding the essential role of "La Dificultad" mine in the history of the mining district and the importance that this place has nowadays as an example of the historical, technological, and cultural heritage. Although these topics are complex, we are trying to explain them in a simple, didactic, and accessible way to all kinds of public through the appropriate resources offered by museography. The use of images, scale reproductions, and interactive examples are designed not only to allow an in-depth appreciation of the subject but its recreation, in such a way that visitors can have access to the necessary information, while at the same time, they can live the experience of touring a real mining site (Fig. 3).

The museum has an important and representative sample of the essential engines to perform mining work. The archaeological materials

consist of an old hoist from the steam era kept in this mine. This represents a rare example in the mining district of an almost intact machine. One of the most important attractions of this exhibition is the steam hoist, adapted to work with electricity so that visitors can see it operating. As a historical complement, illustrations and information cards can be seen and in them the history of hoists, from the ones operated with animal traction to the ones using other forms of power such as steam or electricity, is narrated.

The Andrés Manuel del Río Lithotheque, the drilling cores storage area, houses thousands of core samples boxes and probably, this is the most unusual place of the mine. Visiting it and listening to the explanation of the importance of the geological exploration works can provide an illustrative knowledge of the mineralogical work performed by mining companies. This area has become a mineral sample exhibition room, possibly the first one of its kind in Mexico.

These museums are part of the Silver Route, an important tourist circuit that includes six municipalities in the State of Hidalgo. The scheduled routes take visitors through picturesque mining towns, revealing the richness of the industrial heritage as a learning experience provided by the AHMM (e.g., Oviedo Gámez and Hernández Badillo 2011).

M

Museum Education and Archaeology

Anna Simandiraki-Grimshaw
Department of Classics and Ancient History, University of Exeter, Exeter, UK
Bath Spa University, Bath, UK

Introduction

Archaeology, museums and education are three fields which have, for the most part of their history, been inextricably linked. Archaeological museums are places of learning not only because

they are deliberately created or maintained as hubs of knowledge, but also because they often act as formal or informal actors in debates about identity, communities, as well as the nature of knowledge itself (cf. Stone 1994; Hooper-Greenhill 1996). In this entry, we will consider how archaeological knowledge is communicated and/or facilitated by museums, and we will reflect on the effect and purposes of this.

Definition

I take archaeology to mean both the practice and the subject matter of investigating a past milieu through its material remains (and often intangible survivals), whether this is recent (e.g. World War II archaeology) or chronologically remote (e.g. the Paleolithic). Official practitioners of archaeology are usually certified as professionals by authoritative bodies, such as university departments or (local) archaeological services (e.g. CIfA 2019; Register of Professional Archaeologists 2019).

I take education, more generally, to mean any activity, structured or unstructured, certified and systematic or not, whether in a specifically designed environment or not, which results in a person's or group's learning: the acquisition of new ideas, skills or information which can then be applied to achieve previously unattainable intellectual or practical connections. I take museum education to be the direct or indirect learning outcome of the interaction between museums and their stakeholders, usually (but often not) specifically designed and intended by staff as a mediated experience toward their audiences, on-site, off-site or online (e.g. Stone 1994; Lea 2000).

I take the relationship between museum education and archaeology to mean the proactive/formal or informal education that museums which host archaeology (not just archaeological museums) impart on their stakeholders, usually but not exclusively their visitors (see, e.g., Silberman 1995).

Historical Background

Museums started as educational places which brought together ancient artefacts, curios, objects of beauty and preserved parts of nature, so as to not only serve as collections of information but to also help educate further, first their wealthy owners, then their equals and patrons and then their communities, cities, countries, or (eventually) global audiences (cf. Barker 2010; Schubert 2016; Barrett 2012: 45–80). Archaeology developed from collections of art objects into eventually fully flung collections of art and archaeology (usually combined, even unintentionally). Although museum education with specific reference to archaeology has always been part of the equation, it has developed as a proactive, targeted movement in the last few decades, most notably from the 1980s onward, with a marked proliferation of relevant bibliography from the 1990s onward (cf. discussions in Lea 2000: 317; Barker 2010). Museum education in archaeology developed differently in different countries, depending on the archaeological and museological paradigms of each, influenced by cultural, political and other circumstances (cf. Barker 2010: 296). For example, as will be seen below, a museum with archaeological artefacts operating in a largely conservative regime might offer educational opportunities which emphasize local pride, national importance, and the like, whereas a museum with a colonial history of collections might, in this postmodern, post-colonialist era, reinvent itself by offering educational opportunities which promote ideas of globalization. Overall, however, the shift from the "self-evident" or passive educational role of the museum to its active commission of educational techniques was largely due to the changing role of the museum in general within the context of changes of class and economy, with consumerism, among other things, being a catalyst (see analysis in Barker 2010). It is also due to the increasing role of the museum as a socially engaged and relevant actor.

Key Issues/Current Debates

There are a number of key issues and debates which pertain to archaeology and museum education. Some regard museum practice more generally and others pertain to archaeology more specifically. Several pertain to the role of museums or collections in the imparting, facilitating or even questioning of archaeological knowledge. And although the archaeological museum or collection is usually acutely aware and active regarding its educational role nowadays, it can also impart knowledge in more subtle, indirect or even unintended ways. I categorize the relevant debates and educational processes under eight themes.

Archaeological Method

One of the current debates is whether (and how) to show to the public how archaeology operates, how archaeological knowledge might be arrived at and also why illicit antiquities are problematic (cf. Stone 1994; Argyropoulos et al. 2014). This is often a deliberate attempt to educate visitors and definitely an intellectual outcome of postmodernity, in recognition of the fact that the museum is not the educational be-all and end-all of archaeological knowledge: it devolves the learning experience to visitors, instead of imposing monolithic knowledge on them (cf. Silberman 1995). However, not all museums are comfortable with this approach, and some prefer to avoid this intellectual synergy (expert + visitor = shared knowledge) altogether. In museums which do, however, make this effort, audiences are educated in various ways about archaeological method, e.g. through diagrams of stratigraphy (Fig. 1a), props (Figs. 1b, 7c, and 8e) or displays mimicking a historical archaeological process (Fig. 1c). Visitors other than volunteers, on occasion and unintentionally, may also get a glimpse of other related "behind-the-scenes" archaeological and museological processes which add to their knowledge and understanding of the sector as a whole. Such processes may include re-exhibition (Fig. 1d), storage (Fig. 1e), as well as study (e.g. measurement, moving) and in situ conservation. For example, the author's study of some material at the Archaeological Museum of Chania, Crete, Greece, in 2009 was facilitated by museum staff through stationing the author in one of the museum galleries. In that way, the author and related archaeological work became (unintentionally) part of the museum's exhibits for the visitors to observe for the duration of the research.

Gallery Flows

One of the indirect ways in which museum education in archaeology can be offered is the regulation of gallery flows and the role of exhibits as signposts or focal points. This results in the engineering of visitors' circulation (cf. discussion in Barker 2010: 296–297). Although artefact displays might have been adapted to gallery space, rather than the other way round, often the planned direction of visitor flows indirectly affects their educational experiences of spaces and artefacts. Visitors going through the Aegean collections of the British Museum, situated in a corridor-like gallery (Fig. 2a), will not necessarily focus on and learn about artefacts in the same way that visitors will do for the statue of Nike of Samothrace in the Louvre (Fig. 2b). The former exhibits are more contextualized in their display, and learning about them can be mediated through tours or by visitor engagement with information in the gallery. But the structure of the gallery "funnels" people through, instead of providing a self-contained, cross-referenced environment. Conversely, the Nike of Samothrace is decontextualized as an objet d'art, but its striking focal position and cul-de-sac architectural environment elicit more attention and curiosity from the visitors, whether their learning is active (mediated, acted) or passive (observation). Gallery flows might indeed be designed with particular educational outcomes in mind. The exhibition and gallery spaces of the Parthenon Frieze (Fig. 2c) are deliberately designed so that visitors can see the composition in the round (following the frieze around) and therefore understand its original placing, even though the modern viewing angle is completely different. Similarly, sculptures on podia, rather than against walls or even recesses (Fig. 2d), even when placed in "through-galleries,"

can indirectly educate visitors as to viewing angles, technique, proportions, chronological connections, stylistic development etc.

Art and Exhibition

Museum and gallery architecture is very diverse (Schubert 2016: esp. 99ff., 121–133). Collections may be held in historic buildings, whose original purpose was not museological, or spaces and exhibition cases may be custom-built. These "shells" need also be considered as educational devices: they frame the exhibition philosophy and impart (or even impose) particular aesthetic knowledge and ideals to their audiences. For example, the

futuristic design of the museum at Maa-Palaeokastro in Cyprus is complemented by the minimalist aesthetic of its archaeological exhibition inside and of its landscape outside (Fig. 3a). This is in stark contrast to sections of the Louvre (Fig. 3b) (eadem: 124–128), whose

Museum Education and Archaeology, Fig. 3 (continued)

lavish palatial interiors host artefacts (e.g. statues) exhibited with an art historical rather than an archaeological approach and aesthetic. The purposely built architecture, complete with Mycenaean-style embellishments, of the Prehistoric Collection (the "Mycenaean room") at the National Archaeological Museum in Athens (Fig. 3c) acts as a stage for the finds from Mycenae and elsewhere, attempting to replicate a Mycenaean "ambience." In other examples (Fig. 3d–h), the display of medium- to small-scale artefacts may be hosted within cases or installations which either arrange them in visually striking ways while allowing them to take center stage or create a contrast between the (preconceived) aesthetics of these artefacts and a deliberately (post) modernist aesthetic. Such choices make an educational statement about a particular set of preferred aesthetics, which vary depending on the overall traditionalist or postmodernist agenda of the museum. This, of course, brings us back to the initial purpose of museums: to educate about the art historical or natural world but also to cultivate a particular (overwhelmingly upper-class) aesthetic viewpoint.

Information and Typologies

One of the biggest educational challenges for archaeological collection experts is how to organize information in ways that offer both pleasant and immediate experiences, as well as bite-sized knowledge, toward understanding the exhibits (e.g. Silberman 1995). Some collections offer a richer array of text and/or artefacts (e.g. Fig. 4a) whereas others a more minimalist approach (e.g., Fig. 4b, c). Almost all exhibits, however, are ultimately organized as typologies, the cornerstones of the sector. These are typologies of artefact shapes, such as those of figurines (e.g. Fig. 4b); technologies, i.e. techniques of certain people or periods (e.g. Fig. 4c); assemblages, i.e. artefacts found in the same contexts or site-types or used in the same type of processes, such as trade (e.g. Fig. 4d); or cultures (e.g. Archaic Greek, Fig. 4e). In most cases, they are an attempt to educate audiences in the logic of chronological progressions and stylistic evolutions.

Context and Relevance

Artefacts may appear in exhibition installations which can allude, imitate or even enhance the environment in which these artefacts were originally used or eventually found. This is almost always an artificial and museum-mediated educational trope, but it helps shape the visitors' learning experience through visualization and contemporary contextualization (Johnstone 1998; Forrest 2013). Finds from a burial context (Fig. 5a) can be grouped as an assemblage against a photographic background of the burial context in which they were found (or another one like it), like a vintage photograph taken of contemporary people against a studio background of a landscape or building interior. Although the museum and the visitor know this is an artificial setting, both enter into the process of revisualizing the original context and eventual excavation of these artefacts. For example, artefacts of the Uluburun shipwreck at the Bodrum

Museum of Underwater Archaeology, Turkey, are currently staged in a quasi-replica of the shipwreck, so that the audiences can learn how goods might have been stacked on board or where people would circulate and live on the ship. Reconstructions can go even further by recreating entire living spaces which facilitate a "walk-in" experience: original artefacts might be confined in specially built cases which are incorporated in, and ultimately subordinate to, the overall reconstructed ancient environment. This is the case with an installation of an Iron Age round house at the Museum of the Iron Age, Andover, UK (Fig. 5b). This approach has the advantage of creating knowledge opportunities not only through exhibits and text (visual and auditory knowledge), but also through the sense of space and proportion (physical and aural apprehension etc.). Even if exhibits are not staged within larger simulating installations, they can be made relevant to audience experiences. This is another museum strategy of not only educating but also eliciting connections between ancient artefacts and current, often personal, visitor situations (cf. Johnstone 1998). One case in point are fibulae (brooches) or earrings exhibited against a background of a person wearing these (Fig. 5c). The installation and exhibition of the artefacts may also be deliberately staged against the background of the museum's modern setting (Fig. 5d). In that way, the visitor may be instructed to reflect upon similarities and differences between the world represented within the museum and the one which exists outside it (and of which the museum and the visitor are integral parts themselves). The museum, therefore, can make socially engaged educational statements.

Human Interaction

When museums exhibit artefacts with the intention of educating users, the issue of interaction becomes important, especially regarding representations of humans (e.g. statues, armor) or actual human remains. There are numerous exhibition and education philosophies concerning human representations, depending on the tradition within which the collection operates and the expectations of the audiences (cf. Swain 2006). For artefacts which represent but are not the human body *per se* (e.g. armor), installation is more often than not a propping up of the artefacts in question, so that they *approximate* the human body (Fig. 6a). A particular educational statement is therefore being made about concepts of the human form, humanity, the ancient human experience, etc. In museums which have traditionally operated within an art-historical paradigm, the exhibition of life-size or larger than life human representations might be staged so that the visitors can learn from stylistic, artistic and emotive parameters of the artefacts. For anthropomorphic representation exhibits, people can be provided with space and permission to sketch artefacts as works of art (Fig. 6b), they may be channeled to interact with a room of statues from an upper or lower level (Fig. 6c, d), they may be confronted (and therefore juxtaposed) with an iconostasis of such representations, or they may even be allowed to literally come face-to-face with anthropomorphic representations (Fig. 6e).

The exhibition of and education about archaeological human remains in museum contexts is a very controversial and long-debated aspect of museological and archaeological practice. The debates mainly concern the ethics of the (often colonial or even slave trade) acquisition, ownership and exhibition of human remains (cf. Curtis 2003; Cornu 2009; Kenny 2013). They also concern the degrees of exhibition acceptability, depending on the nature of these remains: e.g. skeletons and bog bodies present different museological and ethical educational challenges. A commendable example is the exhibition "London Bodies" at the Museum of London, UK (cf. Swain 2006). As in this case, often, the human remains, which have an emotional as well as educational effect on the viewer, are installed in an area which one has to choose to visit, instead of an area through which visitors are channeled as part of a more general gallery flow. Consequently, the museum imparts archaeological knowledge in a number of ways: it educates users as to how bodies were deposited and preserved; it sensitizes people regarding the human experience; and it elicits social reflexivity about the ethical choice, made by the visitor, of (not) viewing the body.

Museum Education and Archaeology, Fig. 5 (continued)

Replicas and Hands-on Experiences

Archaeological artefact replicas have long played a valuable educational role (cf. Foster and Curtis 2016; Simandiraki-Grimshaw, Sattler and Angermüller 2020). They used to be a larger part of museum exhibitions up until the middle of the twentieth century CE, especially in the cases of collections or entire museums connected to University Departments of Art and Archaeology. For example, the Museum of Classical Archaeology at Cambridge University, UK, is, in its majority, comprised of replicas. Similarly, the Abguss-Sammlung Antiker Plastik of the Freie Universität in Berlin, Germany (Fig. 7a), is entirely composed of replicas which had had variable origins and biographies prior to their exhibition there (and which can generate further "faithful" replicas for archaeological collections elsewhere). Several museums also exhibit clearly labeled replicas alongside original artefacts (e.g. Fig. 7b), even though the practice is less common now than it had been until the middle of the twentieth century CE. Museums may even make these replicas available to the visitor for handling, as is the case with replica crania in the Origins Centre Museum in Johannesburg (Fig. 7c) or a replica bust of Nefertiti in the Neues Museum, Berlin, Germany. These replicas serve several purposes, primarily educational. Many were created and collected at a time when slides, books and photocopying were very expensive educational means and when the Internet, 3D scanning/printing and online databases did not exist. Several university departments and museums acquired or even commissioned replicas of specific artefacts (often statues), in order to train their students or fill in gaps in the exhibited material. The handling of replica objects also began as a training necessity but has become more prolific in multisensorial education, in the enablement of visually impaired visitors (cf. the Museum of Touch in Athens, Greece). An additional reason for the use of replicas in archaeological education in museum contexts is the creation of an "ambience" (e.g. Fig. 7b). While not necessarily replicating an environment, this rather conveys the atmosphere of the context in which the exhibited originals existed, complemented by the replicas (see discussion of "atmospherics" in Forrest 2013).

Museopedagogy

The most explicit way in which archaeological education is created or facilitated in a museum context is through opportunities for adapted interaction, teaching and further study (cf. esp. Hooper-Greenhill 1996; Lea 2000; Barker 2010). Typically, in-gallery materials may be adapted for different audiences, e.g. different information stands/booklets for adults and for children (Fig. 8a). Another common trope is an interactive or cinema room, sometimes furnished with museum-themed equipment (Fig. 8b), where relevant videos (in 2D or 3D) might be shown. Other types of interactive exhibits might simulate a research environment, whereby the visitor is invited to manipulate technology in order to understand nearby exhibits better (Fig. 8c).

For adults, the museum might organize gallery talks and tours, study days, volunteering (in the gallery, the storeroom or a relevant excavation), or outreach days, such as themed events (e.g. Christmas), tying in with wider and contemporary social occasions or concerns. For children, educational archaeological provision is usually more extensive and tied in, wherever and whenever possible, with the country's national curriculum. Relevant materials are often designed by heritage and education specialists (e.g. museopedagogy experts) on a freelance or permanent basis, depending on the museum's budget. Before their museum visit, children, parents and teachers may be able to consult online materials, e.g. databases, online

Museum Education and Archaeology, Fig. 6 (continued)

games, timelines, lesson plans, worksheets etc. During their visit, they may be given worksheets to complete when going through the museum and locating artefacts or be instructed to draw, debate etc. Children may also be given education packs to borrow or buy, which are tailored to specific exhibits, themes or events. Several museums also offer specialist interactive installations, physical as well as electronic (e.g. the ceramics interactive wall of the Bristol Museum and Art Gallery, Bristol, UK; Fig. 8d), or even mock excavations (Fig. 8e). In addition, many museums have dedicated educational rooms, equipped with props, visuals, dressing-up materials, toys, replicas, information and drawing sheets etc. (Fig. 8f; cf. Fig. 1b). The archaeological collection of artefacts in a museum context thus becomes not just a passive but an active experience, deliberately entered into by both the provider (museum, parent, teacher) and the recipient (child, adult).

In effect, the visitors can nowadays choose their level of educational engagement, from a moderated educational engagement in the gallery to a fully interactive experience online and offline. The philosophy of most museums which host archaeological artefacts, therefore, is to be funds of knowledge and to facilitate an appropriately twenty-first century CE pluralistic exploration of the past (but under specialist guidance and within specialist predetermined constraints).

International Perspectives

This author's archaeological, museological, and educational experience is rooted in the Greek and British relevant traditions and informed by current German museological practice, as well as other sectors and locales, through collaborations, visits or study. It is also shaped by the author's specialization, which lies in Greek (especially Aegean Bronze Age) archaeology, as well as FE and HE educational provision. In this context, I have experienced all aforementioned conditions and approaches at play. The perspective which permeates my understanding of how education operates in museums which host archaeology is one of a number of tensions.

One tension I can discern is between the role of archaeology as the sole object of a museum or as a subset within its larger collections, e.g. natural, artistic, ethnographic etc. (e.g. the Bristol Museum and Art Gallery, UK, the Neues Museum, Berlin, Germany etc.). The educational provision for such archaeological collections may emphasize typological and national knowledge less, instead trying to cast the archaeological materials more as means of understanding humanity across cultures and of understanding how knowledge is formed across disciplines. This is borne not only out of the nature of the once disparate collections which may have accumulated to form a museum. It may also be due to a postmodern need to reinterpret what was once a (quasi) colonial collecting strategy (e.g. the collection of archaeological and ethnographic artefacts, human remains, works of art etc. from a number of countries). There are, however, many cases where the museum solely hosts archaeological material and might indeed have been created with particular material and exhibition philosophy in mind (e.g. the Acropolis Museum, Athens, Greece), either in a traditional, Glyptothek-style, arrangement or a postmodernist, thematic display and educational provision. The tension there lies, especially in many Greek museums, between, on

the one hand, the museum's role in educating about the past and making this relevant to the present and, on the other hand, the museum's role in eliciting pride from the visitor who might perceive the exhibited archaeology as his/her heritage. The museum might even espouse particular archaeological-political agendas (e.g. the return of the Parthenon Marbles, cf. Hamilakis 2011; also see the mode of exhibition in Fig. 2c, emphasizing the replicas which stand in for the original sculptures kept in the British Museum).

Another tension involves the accessibility of archaeological education for museum users. In Greek museums, there is a tension between, on the one hand, making exhibits, their descriptions and their understanding accessible to multiple audiences through e.g. educational packs, online games and guided tours, and, on the other hand, deliberately separating the museum and its professionals from the public, in an obvious confirmation of authority (cf. Ntaflou 2011; relevant general debate in Barker 2010: 297–298). The

latter is done through the use of sometimes inaccessible archaeological terminology (cf. Plantzos 2011), overly typological or chronological arrangements or text-heavy displays. Such tensions might, in fact, exist in the very same museum and enacted by the very same professionals, depending on the situation.

A third type of tension concerns the archaeological education allowed. However inclusive, multimodal and multicultural, the museum still wants and needs to set boundaries regarding what is and is not acceptable. There may be, for example, both archaeologically plausible and archaeologically unsubstantiated interpretations of a particular archaeological artefact exhibited in a museum (e.g. the Phaistos Disc in the Herakleion Archaeological Museum, Greece). The museum, in its exhibition, documentation, guided tours, educational materials, online information, and even souvenir shop, will follow the interpretations which seem plausible to its staff and other experts, without necessarily refuting or even acknowledging competing or discredited interpretations. In this case, the museum regulates the knowledge to be propagated and, usually silently, moderates the official limitations of archaeological knowledge.

Yet another type of tension regards visitors' educational expectations. These vary greatly, according to age, learning style, learning tradition, mood, sole or group visit etc. But the museum can only enable people to pursue particular types of archaeological education, and this is done through all the aforementioned approaches. So, if someone is averse to interactive events, he/she can choose guided tours or sole study during a visit. The key to a successful educational museum provision, in my experience and from my perspective, is the existence of a choice of opportunities for learners to tailor their pedagogical journey. It is also the museum's realization that it ought to educate people toward critical and informed thinking, rather than proselytize them (at least this is the ICOM code of ethics which many museums purport or aim to follow).

Future Directions

Where does the future of museum education in archaeology lie? We need to ask ourselves whether this means where we think the field is heading toward or where we would like it to do so. There is a clear shift globally. Older museological paradigms assumed that museums were "neutral" conduits of knowledge, the latter communicated through an array of selected and categorized artefacts (cf. discussion in Merriman 2000). Nowadays, the tendency is toward more up-to-date paradigms, whereby museums (should) act toward outreach, inclusivity, social relevance, current debate and entertainment (cf. Lea 2000: 317).

However, museums also have to compete for the publics' and learners' affections. Visiting a museum and engaging with its archaeological artefacts at a time of high-tech distractions, such as mobiles, tablets and the like, can be challenging as well as potentially fruitful. It is challenging because the museum visit and its educational elements are seen as an entertainment exercise (cf. Foley and McPherson 2000), on a par with seeing a film or visiting a theme park, with all the pitfalls this equation entails. It is rewarding because the museum, in designing its educational provision, can harness available technologies toward engaging its audiences in ways they are already familiar with (e.g. QR codes, online games, podcasts etc.; cf. Rayward and Twidale 1999; Charitonos et al. 2012). In my opinion, the use of technology as an educational mediator is desirable, but as a component alongside other, multimodal, educational means: props and replicas, physical play and activities, multilingual, jargon-free information panels, community events etc.

In addition, education may be more accessible now, but it is also much more varied. Consequently, the museum is no longer the authoritative educator it once saw itself as, and archaeological educational provision in a museum context is currently trying to redefine itself within a barrage of authoritative and non-authoritative voices (cf. Merriman 2000). There is, therefore, an understandable tendency for museum education in archaeology to engage in wider networks, such as school curricula and online and offline communities, as an educational moderator and controller. With regard to making the collections accessible and relevant, good examples include the

monthly rotation of "unseen" (i.e. non-exhibited) artefacts in the National Archaeological Museum, Athens, Greece; the artistic interventions at the inauguration (June 2009) of the Acropolis Museum, Athens, Greece; as well as thematic events according to yearly occasions, such as an exhibition on witchcraft at the Ashmolean Museum, Oxford, UK, to coincide with Halloween ("Spellbound," 2018–19). In terms of opening gallery spaces and exhibits for the education of local communities, good examples include volunteering, outreach collaborations with local bodies (e.g. schools, archaeological associations), as well as popular publications, lectures and short courses. With regard to educational materials, good examples include the online resources of the Metropolitan Museum of Art, New York, USA; the in-house educational packs and school competitions of the Goulandris Museum of Cycladic Art, Athens, Greece; and the multimodal, interactive elements in the galleries of the State Museum of Archaeology in Chemnitz, Germany.

Archaeology, as field and museum practice, as well as educational provision, has the potential for real social service and even change, as long as it is not distracted by the different purposes and agendas of the elements with which it competes. In my view, the educational role of the museum is to not only impart knowledge about the past but to also participate in current debates, however challenging (socially, politically, disciplinarily) this may be (cf. Stone 1994; Hamilakis 2011). For example, archaeological exhibitions and tailored educational activities about migrations, persecutions, fake news, human trafficking and war atrocities might be difficult. But they would have the potential for social relevance and meaningful debate and would sensitize and educate future generations. In this sense, the museum would not (only) be the propagator of (often class-specific) archaeological aesthetics and interpretations of selected material; it could also redefine itself as a proactive social actor on current debates and pedagogy (cf. Lea 2000: esp. 323–4; Grek 2009; Chan 2011).

Finally, although the aforementioned good examples are not characteristic of many or even the majority of archaeological museums and archaeological collections, in my opinion they represent promising future developments. All in all, museum education in archaeology has the means, drive and potential to emerge, and is already doing so, as an interactive facilitator. In that capacity, it can bridge the past, present and future in imaginative, inclusive and socially engaged ways.

Museum of New Zealand Te Papa Tongarewa

Conal McCarthy
Museum and Heritage Studies programme, Victoria University of Wellington, Wellington, New Zealand

Basic Information

Located in the capital city of Wellington, Te Papa is New Zealand's national museum, which has been innovative, successful, and controversial in equal measure since it opened in 1998. Voted the best museum in the region on TripAdvisor, Te Papa is the most visited museum in Australasia; by mid-2017, more than 25 million people had attended. Its most successful exhibition, *Gallipoli: The Scale of Our War*, which deals with the ANZACs (soldiers from Australia and New Zealand in World War I), has attracted 1.5 million visitors (McCarthy 2018).

Te Papa is the short form of the full name "Museum of New Zealand Te Papa Tongarewa." The Māori name can be translated as a "receptacle of treasured possessions." It alludes to "mother earth" (*Papatūānuku*) in the Māori creation story but can also mean land, foundation, or platform and recalls the traditional *papahou*, or treasure box, containing a rare variety of *pounamu* (greenstone). The "new" museum was in fact not new at all, but a reinvention of its various predecessors: the Colonial Museum founded in 1865, which became the Dominion Museum in 1907, the National Art Gallery and Dominion Museum in 1936, the National Museum in 1972, and finally in 1992 the Museum of New Zealand Te Papa Tongarewa. By the early 1980s, the then National Museum had outgrown its building, and its Māori, Pacific, and history displays were showing signs of being out of step with a changing society (McCarthy 2007). Plans for a new national museum overlapped with, and to some extent grew out of, the groundbreaking *Te Maori* exhibition which toured the USA and New Zealand, 1984–1987. Certainly the museum came under intense pressure for change from Māori leaders

in a period of intense debate about the contemporary relevance of the Treaty of Waitangi, New Zealand's founding document signed in 1840.

The 1985 report *Nga Taonga o te Motu* led on to the establishment of a project development team in 1988 which in turn produced a concept in 1989 recognizing the Treaty and acknowledging the two main cultures of the nation: Māori and Pakeha (European). The new museum was formalized by legislation in 1992 which, controversially for some, integrated the collections of the gallery and museum, leading to criticism from art critics that art should be displayed by itself in a more traditional style.

Opened in 1998, Te Papa quickly exceeded its visitor targets and attracted a large and genuinely diverse audience including an unprecedented proportion of Māori visitors. The outstanding features of the new museum which delighted mass audiences and annoyed academic critics – the interactives, the busy "malled" spaces, the celebration of popular culture, and New Zealand identity – signaled a shift away from the old gallery and museum with their somewhat stuffy image and elite audience. Developers sought to reposition Te Papa within the leisure and tourism industry with a strong branding and marketing drive. This emphasis on accessible interpretation for a broad audience reflected the postmodern tenets of the "new museology," a philosophy which favored the museum as forum rather than temple, and stressed public scholarship and audience-focused exhibitions rather than an inward preoccupation with collections and connoisseurship. These features were seen in other "new" museums in Australia, Canada, and the USA in the 1980s and 1990s, a trend which has generated much debate in the academic literature of museum studies (Message 2006). Into this heady mix of nation building, project management, and museological experimentation was added the distinctive local ingredient of "biculturalism," the idea of two (bi) cultures in one country based on the Treaty (Message 2006; McCarthy 2011). In 2017–2018 the museum was undertaking a renewal of its policy and practice and developing a series of new exhibitions including an increasing emphasis on digital storytelling (McCarthy 2018).

Major Impact

Several aspects of Te Papa could be mentioned as creating an impact on museology internationally, not least the creation of a lively visitor experience and the playful approach to labels and interactives in the multimedia exhibitions. However Te Papa is probably best known for the integration of Māori values into "bicultural" museum practice. A raft of policies define biculturalism: *mana taonga* (see below), *mātauranga Māori* (Māori knowledge/world view), and *tikanga taonga* (Māori practices for managing *taonga* or treasures). These policies were operationalized successfully in parts of the institution – notably collection management and exhibition development – while other areas remained within conventional parameters. Officially Te Papa now saw itself as a *kaitiaki* (guardian, caretaker) rather than owner of taonga and initiated and maintained a complex and at times difficult process of consultation with major tribes around issues such as handling and display of *taonga*, repatriation, human remains, etc. The clearest example of biculturalism at work is Te Papa's functioning *marae*, a ceremonial meeting space where visitors are welcomed, especially the *iwi* (tribes) who are "in residence" every 2 years hosting events and mounting an exhibition.

The central plank of biculturalism is the *mana taonga* policy. *Mana taonga* means literally the power and authority (*mana*) that resides in/derives from cultural treasures (*taonga*). In policy and practice, *mana taonga* is a declaration of the Māori control of Māori *taonga* and consequently a new way of thinking about the relationship of museums and source communities in which anyone who had collections in the museum has the right to participate in their management (McCarthy et al. 2016). The policy had a profound impact on professionals working in the museum project and transformed museological practice in terms of ownership, authority, and identity.

At the level of everyday museum practice, one of the most interesting transformations was the expansion of collection care and management to accommodate the spiritual practices that were necessary for the handling, storage, and conservation of sacred ancestral objects (*taonga*), practices generally (but not always) carried out by Māori

people who form the majority of staff working with these collections (McCarthy 2011). It is worth noting that Pacific collections and exhibitions have also been developed in a comparable way, particularly with the contemporary material culture of Pacific Islanders living in New Zealand (Mallon et al. 2012).

Introduction

While European nation-states were using archaeology and museums to develop their national identities, the latter also started a great diaspora, expanding to the Americas during the first half of the nineteenth century, going hand in hand with the independence of Spanish and Portuguese colonies (Swain 2007). Like their European counterparts, the new American nation-states were constructed following the ahistorical principle of homogeneity (Gnecco 2002) unifying their peoples through the appeal to a singular past and a sense of commonality, excluding and denying the existence of culturally differentiated groups within them (Benavides 2001).

American museums are associated with colonial practices of excavation, collection, and exhibition of human bodies and indigenous objects. Through these devices, archaeology provided the scientific means to demonstrate the racial superiority of the colonizers and justify the dispossession of indigenous lands, knowledge, bodies, and collections. With the establishment of nation-states, both museums and archaeology contributed to nationalist discourses (Díaz-Andreu 2007), either through their interpretations or through the material evidence that allowed constructing the history of these new imagined communities (Anderson 1991). The early enactment of laws that reaffirmed the state ownership of archaeological heritage also implied the heritagization and nationalization of indigenous archaeological bodies and objects (Rodríguez 2010). Parallel to this, European culture and values prevailed over those of indigenous peoples, who were considered part of the past and were therefore subject to domination and museization.

It is impossible to dissociate the museums' histories from the histories of indigenous peoples that inhabited and inhabit the current national territories. In the last six decades, it is also difficult to separate museums and archaeology from indigenous struggles over their cultural, territorial, and sovereign rights (Fine-Dare 2002). In this context, indigenous leaders and intellectuals have questioned the colonial scientific practices of excavation, collection, and exhibition (Deloria 1988; Mamani 1989), as well as the treatment of their ancestors and sacred objects (Fforde 2002; Garcia 2016). In North America, decolonization activism was identified with the "Native American Museum Movement" (Arthur 2014), at whose

heart the activism of repatriation and reburial was installed (Riding In 2005). In South America, the indigenous critique to archaeologists and museums occurred more recently, especially from the 1990s with the implementation of multicultural policies and the visibility of ethnic demands (Gnecco and Ayala 2011). The lack of participation, community permission, and information about research projects, as well as their demands to manage archaeological sites and museums, is central to indigenous claims. The excavation of cemeteries, exhibition of human remains, and removal of objects from their territories are also critical aspects within indigenous contestations. While there is a great diversity of indigenous peoples in the Americas, several of these demands, in some cases all, have been used as banners of criticism toward archaeology and museums by indigenous leaders and intellectuals. The crisis of representation of archaeology and anthropology and the discussions regarding their authoritative voice to speak for or about the "other" have also been at the center of this debate, while indigenous peoples claim they are the ones who must speak for themselves (v.gr. Deloria 1988).

The repercussions of indigenous activism have been visible in museums, which aside from critically assessing their histories have also generated discussions about new practices and methodologies for indigenous inclusion and decolonization (Lonetree 2012; Phillips 2011). Criticisms regarding the treatment of indigenous sacred bodies and objects stand out not only because of their repercussions on national and international laws and codes of ethics but also on working protocols for collections and exhibits (Fine-Dare 2002; Endere and Ayala 2011; Arthur 2014; Ametrano 2015). There have also been important changes in archaeology and despite being marginal approaches with respect to dominant archaeology, new forms of relationship with indigenous peoples are currently being sought through decolonial, public, community, collaborative, and indigenous archaeologies (Watkins 2005; Smith and Martin Wobst 2005; Atalay 2006; Colwell-Chanthaphonh and Ferguson 2008; Silliman and Ferguson 2010; Montenegro 2014).

In the following pages, we will address these and other debates, focusing on the case of the Museum of San Pedro de Atacama and the relationship of its archaeologists with the Atacameño indigenous people. We believe that a critical analysis of its history and taking charge of it will allow us to shed a light over new types of relationships and collaborative works between archaeologists and indigenous peoples. As Shepherd said in the Virtual Forum: Archaeology and Decolonization: "Before understanding or appreciating where we want to go or what we want to become, we need to understand what we have been and the forces and contexts that have made us what we are" (Haber and Gnecco 2007: 404–405).

A Brief History of the Museum

The Atacameño people are the indigenous inhabitants of northern Chile; their homeland centers around the Atacama Desert (Region of Antofagasta), known as the driest desert in the world (Fig. 1). The extreme aridity of the environment has favored the preservation of archaeological sites and objects, organic materials such as wood and textiles, and where naturally mummified remains of human beings are not uncommon. For this reason the Atacama Desert has become a center of archaeological research. The Atacameños have coexisted with archaeologists for more than a century and with the Archaeological Museum of San Pedro de Atacama for 60 years. Throughout their history this indigenous people has undergone a series of drastic changes, from the Spanish conquest to the establishment of the Chilean neoliberal multicultural state. These changes are reflected in their integration to industrial mining in the twentieth century and more recently to the tourism industry, which has led traditional agropastoral economy to a secondary position (Vilches et al. 2015). Another consequence of this process was the loss of their language Kunza; the last native speakers of Kunza died in the 1950s. Despite these changes, the Atacameños retain their cultural traditions. In the last 20 years, a process of recognizing and strengthening their identity has

Museum of San Pedro De Atacama, Northern Chile, Fig. 1 Region of Antofagasta, traditional homeland of the Atacameño people. (Map by Mariana Ugarte)

made them critical stakeholders in the archaeological and political courses that affect them (Ayala 2008, 2011).

Archaeology in the Atacama Desert began shortly before the territory was annexed to Chile following the War of the Pacific with Bolivia and Peru in the late nineteenth century. The interest of the Chilean government to assimilate the indigenous peoples that inhabited this region prompted the development of archaeology, as it was important to know the indigenous past to carry out this process. Moreover, producing and possessing information about this territory (geological, archaeological, sociocultural) was a strategy of symbolic ownership amidst border disputes (see also Romero 2003; Ayala 2008; Kalazich 2015).

In the first half of the twentieth century, several local and foreign archaeologists were investigating in this area, including Max Uhle (v.gr. 1913), Ricardo Latcham (v.gr. 1936), Aureliano Oyarzún (v.gr. 1910), and Grete Mostny (v.gr. 1949). However, the arrival of Gustavo Le Paige in 1953, a Belgian Jesuit priest and amateur archaeologist, was crucial to the development of archaeology in the Atacama as well as to the notoriety of this region internationally. He conducted excavations at a variety of sites along the Atacama Basin, rock shelters, mountain-top ritual sites, open camps, and lithic quarries, although it was the excavation of funerary contexts which characterized the focus of his work as well as the provenance of the collection (Núñez 1993). It was with these materials and human remains that Le Paige inaugurated the Archaeological Museum in 1957 in San Pedro de Atacama's Parish House (casa parroquial). In 1958 this museum was incorporated to Universidad del Norte. In 1962, the priest began the construction of a purposefully built precinct to hold and display the ever-increasing archaeological collection, which he did with the aid of military conscripts, Atacameño builders and some of the Atacameño children that usually accompanied him in his excavations (Núñez 1993). In 1963, during the celebration of the First Chilean Archaeology Conference in San Pedro de Atacama, Le Paige inaugurated one pavilion of the new building. Later, two more were built and the museum finished with a total of three pavilions: one for the permanent exhibit, another for laboratories, offices and the library, and a third one for the storage of the collections. In 1991, with contributions from Minera Escondida, the Treasury Room was built to display the golden objects collection. (The collection is made mainly by golden vases and plaques from the Larache archaeological site in San Pedro de Atacama. Minera Escondida Limitada, operated by BHP Billiton, which provided the funds to build the room is one of the largest transnational mining companies in the Antofagasta Region. Through CSR image-cleansing policies and Fundación Minera Escondida the company channels resources to fund educational and social participation programs in the Antofagasta Region.) This building would work, with some later additions, until 2015, when it was demolished for the construction of a new museum.

After the death of Gustavo Le Paige in 1980, the direction of the Archaeological Museum of San Pedro de Atacama was taken up by various archaeologists who motivated the flow of visiting researchers and the increase of its permanent academic staff. In 1984 the Instituto de Investigaciones Arqueológicas y Museo (Institute of Archaeological Research and Museum – hereafter IIAM) was created, from the merger between the Department of Archaeology at Universidad del Norte (later to become Universidad Católica del Norte, UCN) and the Archaeological Museum of San Pedro de Atacama. While the growth of the academic staff has been gradual over time, from 2006 onward the number of researchers has increased with the opening of their postgraduate programs (in which the doctorate program is taught jointly with Universidad de Tarapacá in Arica).

In 2002, the Museology Area was created, initially, to stabilize the archaeological collection left by Le Paige and his successors, since a majority of the objects and human bodies of this collection were damaged by the absence of conservation treatments and appropriate storage facilities. Due to increasing contestation to the museum by the indigenous community, this task became an institutional priority in those years. Shortly after the museographic work to improve the permanent exhibit and create temporary exhibitions began. After 20 years of the exhibit created by Le Paige, in the mid-1980s the museum opened a new permanent exhibition to the public. Because human bodies continued to have a central role in the new museographic display, indigenous leaders demanded their removal from the exhibition. For this reason, renewing the permanent exhibit also became an important goal for the museum in the twenty-first century.

In 2004, due to the increase of indigenous criticisms against the museum, also related to demands of community participation, having a

voice in excavation permits, the management of sites and the museum, as well as the custody of archaeological heritage, the Unit of Relations with the Atacameño Community (URCA) was created. This area of public relations was especially focused in building and maintaining the ties between the Atacameño people and this institution (Ayala 2008, 2014). It was also in charge of the heritage education program called Andean School (Escuela Andina). The Area of Education was created in 2009, with the aim of promoting and disseminating the local cultural heritage through guidance services and educational activities. The opening of these new areas generated several changes within and outside the institution, since previously the IIAM had been characterized by a strong emphasis on research, leaving aside the development of museological and educational programs.

After almost 50 years of operation, in 2009 the museum was found to have structural damage which deemed the building dangerous for both people – museum workers and visitors – and the archaeological collection. Although at first the university had planned improvements to the building, the regional government got involved laying out a multimillion-worth project financed by the National Fund for Regional Development through a loan from the Inter-American Development Bank. The idea was to establish an ultra-modern and spacious museum in the so-called archaeological capital of Chile, to be administered jointly by Universidad Católica del Norte, the Consejo de Pueblos Atacameños (Atacameño Peoples Council), and the state (Regional Government and Municipality of San Pedro de Atacama), through a form of organization and structure that has not been defined yet.

The construction part of the project implied the total demolition of the previous structure, for which it was thought in two stages: first, the construction of a temporary precinct to hold the entire archaeological collection and locate the research space for permanent staff and visiting fellows while the construction of the new museum took place. The conservation consultants worked with the Le Paige museum conservation team during 18 months to properly catalogue and establish all conservation measures to move some 400,000 objects, 5000 human skulls, and 400 mummified human remains. The second stage is the construction of the new museum, which was to begin in January 2015 and be finished by March 2016. This step could not start until the entire collection was safely moved and stored in the temporary facility. The movement of the archaeological collection was finalized in 2016; it was composed of some 12,000 boxes of various materials. The temporary structure was built with the appropriate infrastructure according to the requirements of conservation of the collection, guaranteeing its protection as long as needed. It also includes spaces for the continuity of the research activities conducted at the institute and museum: laboratories, offices documentation center, and classroom, among others. There were, however, several problems with the implementation of the second stage of the project, as to this date the new museum has not been built. At the place lay the ruins of the old museum, which was partially demolished shortly after the collection was moved.

Since the new museum project implied a new but unknown organizational scheme with other stakeholders, between 2015 and 2016 the IIAM took precautions to safeguard both its research unit and archaeological collection, therefore "dividing" the IIAM into the Instituto de Arqueología y Antropología – IAA, and the Museum R.P. Gustavo Le Paige, each with its own director, but under the umbrella of the IIAM.

In 2017, the IIAM opened a communications post, which has had an important role over the last 2 years in the development of outreach initiatives and the activation of institutional social networks. The ninth version of the Andean School was applied for by this unit, participating also in the publication of an archaeological atlas for children (see Figueroa 2018) and a series of lectures on heritage and conservation. Due to the "temporary" location of the IIAM in the outskirts of San Pedro de Atacama (Fig. 2), the use of social media and regular news updates in the website and local newspapers have been fundamental to maintain links with the town and its publics.

M

The Museum's Relationship with the Atacameño People

The Beginning and Professionalization of the Museum

Since its inception, this institution showcased the scientific work of Le Paige and his desire as a collector. Le Paige excavated a variety of archaeological sites with an emphasis on cemeteries. As mentioned before, Le Paige and the archaeologists who came after him eventually collected over 5000 human skulls, 400 mummified human remains, and 400,000 objects. Therefore, the exhibits of this museum were characterized by the presence of human bodies and funerary objects from pre-Hispanic tombs. While Le Paige was one of the defenders of the historical continuity of the Atacameños, this was not meant to validate their opinions. The Atacameños' critique referring to Le Paige's archaeological work is mainly associated to the excavation of hundreds of burials, a fact that seen in the context of local practices and discourses from that time went against their values and beliefs (see also Spahni 1967: 131–132). The Atacameños refer to archaeological sites as places of the *abuelos* (grandparents) or *gentiles* (heathens), spaces and things that must be respected and feared in which the "land or the abuelos can catch you and get you sick," reasons for which they should not be disturbed nor visited, or objects taken from them. The *abuelos* are the ancestors of the Atacameño people. Le Paige was aware of these local beliefs; however his scientific interest for Atacameño archaeology led him to deny the practices and discourses of the indigenous population, together with the cultural meanings that the archaeological remains portray for them. His attitude was not only coherent with the political context as well as with the development of archaeology in those years but also with his practice as a priest by which he must have had considered important to eradicate these "pagan beliefs" in a crusade of his own, similar to the "extirpation of idolatries." Taking into account the power of Le Paige as a scientific-religious authority in a social and political context that did not favor indigenous peoples, it was difficult for Atacameños to express their disagreement regarding the excavation of archaeological burials (Ayala 2011).

> There were people who were outraged at him but also I do not know if they manifested it or showed it in a soft way or in very different ways that made him rethink his attitude regarding the work he was developing as archeology. (Atacameño 1, 2004) (By petition of the majority of the people interviewed, their names remain concealed (Ayala 2008).)

Also, some people stopped attending mass because of their strong discontent with Le Paige archaeological activities:

> . . .with Father Le Paige many people drifted apart from the church when he started to work the archaeological part because well, the father did not hide much what he had, he had a lot of skulls. (Atacameño 2, 2003)

In this context, Le Paige reproduced colonial relations of denial with the Atacameños, since, despite knowing of the disagreement the communities held regarding his archaeological practice, he continued excavating cemeteries and displaying human bodies, which created a distance between the museum and the local community. Discrepancies surrounding his archaeological practices were also rose in the private realm, in the families where children that accompanied Le Paige to archaeological sites were reproached, a context in which these fears were not expressed to the father.

On the other hand, Le Paige was aided in his excavations by some Atacameño children that would later be part of the staff of the museum, as well as some of their offspring. Their words about Le Paige are of gratitude and kindness; most of them are or were practitioners of Atacameño traditions and concerned with the dissemination of their culture. Every year, the Atacameño families close to the priest organize a mass and luncheon for his birthday, to which all museum and institute staff are invited.

Le Paige was concerned with the objects staying in the region instead of being shipped elsewhere, entering private or public collections in some distant country or other cities of Chile (Le Paige 1957; Núñez 1993); the looting of archaeological sites had already began, so the

priest would tell the children to let him know first if they heard of any discovery, which he rewarded with powder milk and other groceries. At least that way the objects stayed in the region (Núñez 1993). In addition, not only did the father conduct archaeological digs following his own explorations, but also people would approach him and tell him about archaeological remains they had found in their lands or directly took objects to him.

Thus, the relationship of Le Paige with the Atacameño people, although framed within structural asymmetrical power relations characterized by the denial of ethnic agency, had also some nuances, especially in the relationships built between the priest and the people closer to him (Ayala 2008, 2011). (For an interesting study of the religious, political, and intellectual career of G. Le Paige, linked to the analysis of republican colonialism, military indigenism, and the history of local anthropology, see Pavez 2012.)

During the late 1960s, doctoral researchers from Columbia University conducted their studies in the Antofagasta Region. They came with grants from the US National Science Foundation (NSF), the Chile Exploration Company (Guggenheim brothers), and the Chuquicamata Copper Company, PLC, a joint society between the Chile Exploration Company and Codelco (see, e.g., Pollard 1970; Druss 1976). US public-private involvement in foreign research contributed to the dissemination of positivistic theoretical frameworks in Chilean archaeology, exhibiting the traits of imperialist archaeology (see Trigger 1984). (US research interventionism abroad had begun with Project Camelot (1964–1965) (Galtung 1968), with Latin America as one of its priority regions. Although the project was short-lived, as seen above funding continued being allocated to foreign research in different fields of the social sciences.)

With the death of Le Paige and the arrival of new archaeologists in the 1980s, there were some changes to the museum. These changes were framed in a more professional approach to archaeology and the replacement of some exhibits from the time of Le Paige. However, the new exhibits continued to represent the Atacameños as part of the past and continued to use human bodies and funerary objects. Parallel to this, archaeologists continued excavating cemeteries and thus continued transgressing and denying local beliefs regarding the *abuelos* or ancestors. Therefore, the local community perceived the museum as a place of exclusion and was regarded with distrust. Some Atacameños claim that they "hated" this institution and forbade the entrance of their families to its facilities.

> There were at least 10 years of torment, of madness. Of torment really. I came to think that 80% of the town people were against us and the remaining 20% was indifferent.... I'm talking about that period at the end of the 80's. And I thought that all the effort that I had done was worthless because things did not improve, they were worse and the attitude of the Atacameños, at the same time they begin to accept their atacameñidad, they rejected it more. (Archeologist 6, 2004)

Despite this conflict some attempts were made by archaeologists to include the local community through guided visits to archaeological excavations. These activities were well received by some member of the Atacameño community: "Look, I think it was a pretty relationship, at least I had a good experience, but that was me, this was around 82" (Atacameño 2, 2003).

At the time, the national context was that of Pinochet's dictatorship (1973–1990). Despite the closure of universities and/or academic departments, and the persecution, detention, and disappearance/execution of social scientists all along the country (Garreton 2005), San Pedro became some sort of a safe haven for archaeologists to continue developing research. The appointment of a military rector at UCN that was an archaeology and anthropology enthusiast was quite significant for the survival of the discipline and its practitioners in the region. In parallel, historizing critical geopolitical spaces, such as the regions of northern Chile – which had been until the 1900s part of Peru and Bolivia – continued to be an important strategy of territorial control, as it was also at the wake of the twentieth century (see above; Ayala 2008; Romero 2003). In addition, the presence of US scholars in the region must have deemed this region as non-insurgent.

The Museum in the Multicultural Era

With the return of democracy in 1990 after 17 years of dictatorship and the enactment of the Indigenous Law in 1993, Chile started to be represented as a multicultural nation and thereby active in imposing a change in relations between the state and indigenous peoples. The reconfiguration of the Chilean state in the democratic period goes hand in hand with the installation of neoliberal multiculturalism, which generated a new ideological, legal, and institutional scenario oriented toward indigenous peoples. With the participation and recognition of cultural difference as a new art of government, culture began to occupy a central place in public debate and in the identity construction of indigenous populations and the new Chilean nation. Since the state had previously disseminated a nationalist discourse of rupture between the indigenous past and present, the multicultural political discourse changed the relationships of these populations with their past, when the Indigenous Law suggested that the ethnic groups are descendants of pre-Hispanic societies. This law also integrated indigenous peoples to the national history, and this led Chilean people to reimagine themselves as a multiethnic nation and to reinvent themselves through a long-standing linear temporality, which places the pre-Hispanic past at the origins of the multicultural Chilean nation. On the other hand, the re-elaboration of the past of ethnic groups in Chile has been a process of readjustment, tensions, and contradictions between the preexisting notions of identity, ancestrality, and temporality and those imposed by the multicultural state (Ayala 2014).

Initially, the Indigenous Law did not consider the Atacameños as one of the country's ethnic groups; the Atacameño leaders needed to meet a number of demands of information to be included in this legislation. The information requested included archaeological research to validate their historical continuity. In this context, Atacameños went to the Museum of San Pedro de Atacama looking for antecedents as an indigenous people. Together with archaeologists they gathered information that could guarantee the chronological depth of this ethnic group, traveling later to the capital Santiago to process their recognition. Once legally recognized by the state, the Atacameño raised a number of criticisms and demands against archaeology and the museum of San Pedro de Atacama. However, archaeologists of this institution "were locked in a glass bubble" according to the director at that time, Agustin Llagostera, and denied the indigenous demands. Archaeologists were increasingly immersed in their research problems. Under these circumstances, archaeologists were involved in disputes over control and rights to archaeological heritage. This was clearly reflected in the process of protecting and managing archaeological sites, driven by the state and ethnic groups. In this case, archaeologists were engaged in political alliances that sought to define the ownership of indigenous heritage and the type of projects to be conducted.

During the 1990s, the museum's exhibition continued stereotyping the Atacameños as part of the past, and the human bodies continued to occupy a central place in the exhibits. At the same time, ethnic leaders claimed they did not feel represented by this institution and made demands that they no longer wanted to be treated as "museum pieces" and said "were a living culture and not mere objects." In this scenario, while the Chilean multicultural state acknowledged the existence of the Atacameños in this decade, the museum of San Pedro de Atacama perpetuated the image of decline of these populations by focusing on pre-Hispanic periods in its exhibits.

For four consecutive years, every October 12 (Columbus Day) the Atacameños lit candles in front of the museum in San Pedro de Atacama, in consideration of the ancestors held by the museum. Leaders of the indigenous group Zhali Lickan Ckappur once took over the museum, in circumstances that the professionals of this institution do not acknowledge saying: "It was not a proper takeover." At the same time, Atacameño workers from this institution remember this event:

> 2002 seems to me, 2001, because it was the last protest they made. They arrived at the Museum around 4 in the afternoon and entered. They threw, well, a *llijlla* (Andean textile used for ceremonies) on the floor, they put coca leaves ... [they started] doing a *pago* (Offering to Mother Earth

> (Pachamama)) there. You did not really understand what it is because it had no *aloja* (Local drink made with the pods of *Algarrobo* (*Prosopis*) trees), it did not have *coca*, it did not have alcohol that was the other drink that the old people consumed ... nothing, at least corn *chicha*, nothing. So making a *pago* with what they never consumed is like weird. Also on the flexit floor they were not going to be able to throw it to the *Pacha* (Mother Earth), nothing. Then they were there talking a few words and then went out and there again began to make a *pago* at the entrance, on the right, there they knelt and there they were giving the fight.(Atacameño 6, 2004)

According to the archaeologists working at the museum, these events were treated with indifference because, "we were very distanced, we had devoted ourselves to the scientific academic work" (Archaeologist 7, 2004). In 2000, on the eve of October 12, there was an attempt to burn down the Museum of San Pedro de Atacama. For the archaeologists from the museum, this was a manifestation of the Atacameño community, they stated that this was "the climax of the rupture between the institution, academia, and the indigenous community" (Archaeologist 7, 2004). The situation was not handled as an institutional problem associated with the relations with the community but as a danger for the museum and the archaeologists.

> No substantive decision was made. Because for me the underlying situation was not only to recognize the need that we had to be more active with the community, not to be something so alien to them, but to do something. (Archeologist 6, 2004)

This distancing of relations, or lack thereof, evidences a denial of the Atacameños as a subject of interaction – the denial of their right to have an opinion about archaeological practice and a lack of acknowledgment of the value of such opinion. Despite the existing demands and critiques to the discipline, the archaeologists have ignored them and marginalized themselves from the process.

In response to this conflicting context, in 2001 there was a change in relations between the museum and the Atacameños; the institution began to take actions to address the problem. However, this was accomplished without an internal discussion concerning relationships with the indigenous community. The museum began its process of openness to Atacameño participation without a clear policy. First, in 2001 the museum organized "roundtable discussions" with leaders of the Atacameño community. Some participants in the first discussions found it somehow "cathartic" with moments of tension between archaeologists and Atacameños. At the second discussion in 2003 according to some ethnic leaders, a new museum project was announced without much dialogue; for the archaeologists it was an opportunity to communicate about the activities they were carrying out. In 2005 the third discussion took place with the aim of acknowledging the perceptions, interests, and sensibilities of the local population, with the intent of opening discussions so as to create an institutional policy regarding relations with the community; however these discussions did not produce a clear policy.

In 2002 the Andean School was created, an annual program of heritage education from which scientific discourse is disseminated from within the museum and other universities in northern Chile. Since its inception this project was funded by national and international institutions (National Monuments Council, National Indigenous Development Corporation, Origins Program/Ministry of Development and Planning/ Inter-American Development Bank); thus their approach is strongly associated with state indigenous policy. This program had 20 places for Atacameño students who had classes in archaeology, anthropology, history, geography, ecology, and heritage. In the first 8 years of this program, there was a growing interest from the Atacameño community to be a part of the Andean School. In 2008, this program became a Diploma on Heritage Education. Talking about this school, the Atacameños assume the lack of technical skills in their communities: "we need technical advice, technical support, technical assistance: lawyers, anthropologists, archaeologists, but positive, not negative, with a high point of view, not that speculate" (Atacameño 8, 2004). Also, the Atacameño students used their participation in the Andean School as an opportunity to present old and new demands to the museum. Until today, it is a program that has significant impact in transforming the relationship between this institution and the indigenous community. It has also influenced the

changing public image of the museum, which is now represented as an open space for indigenous participation. The Andean School operated for eight seasons and was then shut down in 2010 due to lack of funding and matching agendas. As will be seen in the following pages, this program will open again in 2018.

As mentioned above, the institutional opening produced by the Andean School led to the creation in 2004 of an area specially dedicated to ethnic ties with the museum, the Unit of Relations with the Atacameño Community (URCA). This position was in charge of the formulation and execution of outreach programs, organization of dialogue tables, the reception and answer to petitions for professional consultancies, or the museum's participation in community activities. The work developed through a mediator was welcomed by indigenous communities and associated organizations since they had a specific person in the museum to make demands and petitions. However, an important issue brought about with this modality was that it was a way of establishing a relation with the Atacameños from the outside, since the direct relation was delegated to a mediator. The political and strategic character of this position must not be overlooked, which was created as a response to the conflicts risen between archaeologists and the Atacameño community (Ayala 2011). This area was shut down in 2011 due to changes in the direction of the IIAM.

Parallel to this PR position, the institution initiated a community museum outreach program and a research project developed by the Atacameños on Atacameño ethnoastronomy. In 2007 the museum removed the human bodies or *abuelos* from the permanent exhibit after a year of bimonthly meetings between museum professionals and community representatives. At the same time, modifications were made to the museographic display text including a brief story about the history and contemporary life of the Atacameños. With these actions the museum began the process of accepting the Atacameños as the historical occupants of the land and their status as a living culture.

It can certainly be said that there has been a major shift in relations between the museum of San Pedro de Atacama and the Atacameño community since the beginning of this century. However, it cannot be said that the museum has decolonized its archaeological practices. In analyzing the inner workings of programs developed for indigenous participation, power asymmetries have been reproduced by this institution. Mainly that the decisions made concerning indigenous participation have been made without the participation of the Atacameños.

The roundtable discussions conducted by the museum have not always considered the concerns of indigenous leaders. In addition, these meetings had no set agenda; in 10 years there were only three meetings of any importance to the Atacameño community. On the other hand, while the Andean School created a space for the participation of the Atacameño people, the museum limited and controlled their participation. In fact, the Atacameños were integrated as students and visitors of this institution and did not participate in decisions about the Andean School program or the museum. An example of this was the indigenous demand that Atacameño teachers be included on an equal footing with the professional teachers employed by the Andean School; this demand was unmet by the fact that the museum decided the level of inclusion of these Atacameño teachers. Another disconnection was between the discourse of community involvement of some teachers of this program and their professional practice. Some of the archaeologists who taught at the Andean School were involved in environmental assessment projects that threatened the interests of the Atacameños. This has been one of the strongest criticisms from the Atacameño community (Ayala 2008; Marcos 2010). (At present, and as part of a commitment to ethical research, IIAM academics do not participate in environmental impact assessments or act as consultants for the mining companies operating in the area nor do they participate in calls for grants made by these companies.)

The program to remove the human remains from the permanent exhibit has been criticized both by researchers at the museum and Atacameño leaders. It was considered that the representation of indigenous communities was

not inclusive enough. However, its greatest effect has been to silence the discussion of the reburial of archaeological human bodies or *abuelos*. This was one issue that the museum was not willing to discuss in those years; the bodies were removed from the display only to be deposited in storage areas specially constructed inside the museum.

The absence of an institutional policy that guided the participation of the indigenous community has affected the programs undertaken by the museum. Until today, the characteristics of the indigenous programs as that of education and outreach programs depend more on personal rather than institutional agendas. Therefore, changes in management affect the way forward in the ethnic relations and resources allocated to it, which historically have been scarce. This was more than clear with the closure of URCA.

As we saw in previous pages, when analyzing the spaces of indigenous participation opened by the museum in San Pedro de Atacama, the educational, public relations and management of archaeology aspects stand out, which has been installed as the new disciplinary format and the "must" be for many professionals. This tendency conforms to what Ayala (2014) defines as multicultural archaeology, an approach which recognizes indigenous people, opens archaeology to their participation, or accepts the indigenous property of heritage. However, this ends up being a mere formalism to continue practicing an archaeology rather than questioning its power and place of enunciation (see Dawdy 2009; La Salle 2010). It is a traditional archaeology that conforms to the mandates of multiculturalism, a waist adjustment characterized by talks and outreach courses that promote "restricted and controlled indigenous participation." Eventually, this is followed by the participation of community members as labor in the excavations and the cleaning of materials, without having a voice in the design, formulation, development, interpretation, and/or results of the project itself or in the taking of decisions on recovered collections (see Kalazich 2015). However, it is also true that multicultural archaeology has opened up spaces of indigenous participation that did not exist previously, as well as debates on the social and political consequences of archaeology highlighting the difficulties of articulating theory and practice in building new relations with communities.

The Demolition of the Museum Building

In recent years, the demolition of Le Paige's museum in 2015 produced new conflicts with the local community. The new museum project included both the building (storage space for the archaeological collection, laboratories, offices, exhibition spaces) and the museography: scripts (written discourses) and displays (visual discourses). Because public funds were to be used, the project was executed through a national request for tenders, thus outsourcing a decision-making process that by all means required local participation and discussion. The project had been submitted as an Environmental Impact Declaration (DIA in Spanish) to the Environmental Impact Assessment System (SEIA) and within it to a public consultation process. Such consultation is more of a screen, non-binding and participation is minimal. Indigenous communities would later claim that the project should have gone through indigenous consultation as established by the 169 ILO Convention (which is also non-binding, but the forms of participation are more accepted by indigenous communities than the former).

This project also created different reactions within the diverse stakeholders involved in or affected by cultural heritage decision-making, social science and heritage research sectors, the local communities, professional unions, scientific societies, the institute and museum staff, and tourism operators, among others. Some were enthusiastic about the idea of an avant-garde museum in San Pedro de Atacama's main square; it would contribute to the quality of the services offered to the tourists, boosting the town's notoriety worldwide. Others emphasized in the improvement of the storage conditions, especially that of the *abuelos* or Atacameño ancestors. In this regard, the measures taken by the conservation specialists were not only technical as to meet international conservation standards with acid-free boxes, barcodes, and a thorough documentation of the collection but also, and more importantly, were

borne out of a profound respect and care for the ancient ones, built on local knowledge regarding funerary practices and rites, which was possible due to the work of Atacameño women in this unit.

Some were critical about the architectural design of the new ultramodern museum; its size, construction materials, and design proper were put into question due to its location in a rural town; the emphasis should be on the local communities, not necessarily the tourists, some said.

Yet others were concerned with the legacy of priest Le Paige. The museum building – its materiality – was, after 60 years, part of the cultural heritage of San Pedro de Atacama and its history, of the history of archaeology, and of the archaeological heritage of this region. Thus, it should have been preserved as a ruin, an archaeological site, locating the new museum project elsewhere. How is it that heritage professionals seek to erase critical aspects of San Pedro's past? It seemed illogical to some that the National Monuments Council would authorize the demolition of a building that had such an impact in the town. For others however, it was part of a history that was better to erase, which also speaks of the impact of the museum, both materially and symbolically. Anyhow, the land on which the museum was built was private property but ceded in perpetuity to UCN as long as it continued to have a museum in place; thus building the museum elsewhere was not an option.

Unquestionably, the museum building was not in conditions to continue storing the collection or being habitable for much longer. The heavy winds, occasional sand storms, and rain were a threat to the museum's dead and living. But maybe, it needed not to be completely destroyed; the new museum could have incorporated an architectural testimony of Le Paige's museum within its structure, for example. There seemed to have been a lack of discussion regarding what heritage is, its meanings, histories, and purposes, that went beyond the regional government's desire to carry out such a project, and focused instead on a local scale, on a situated architectural and museographical design.

Parallel to this process, with both the opening of a communications position at the institute and a current administration more sensitive to indigenous claims at both university and institute level, several steps have been taken on the side of education and outreach, such as the reopening of the Andean School in its ninth version; the opening of a small exhibit at the temporary precinct, which displays a part of the archaeological collection organized by materiality; and a more straightforward communication with some indigenous communities and the Atacameño People's Council, which is also fueled by a new set of relationships and interests.

Regarding the Andean School, its relaunch in 2018 was related to the ever-growing interest on behalf of the local population – native and non-native – in the local past, in acquiring scientific knowledge and tools, especially with the growth of tourism on the one hand and the ever-present mining industry seeking to exploit the resources found within their ancestral territories on the other. The funding for this new version of the Andean School was obtained through a grant from the National Funds for Culture and Arts; most teachers and the facilities used were provided by the IIAM and also included Atacameño teachers. The Diploma consisted of nine modules taught by specialists in each area: environment and first settlers of the Atacama; Center South Andean iconography; geo-heritage; rock art; symbolism, celebrations and rituals in the Andes, and linguistic heritage; state, communities, and political ecology; multivocal values of cultural heritage; and heritage conservation. Like in previous years, this program received a high number of applications; from 70 applications 30 were selected, of which 22 were Atacameños. One of the current problems of the Andean School, as stated for previous versions, is the lack of permanent funding, thus subject to competitive grants that may or may not pull through.

The museum exhibit at the temporary precinct emerged after the realization that the stay would not be that temporary but could rather last 5 more years. Due to the location of this temporary precinct slightly outside of the town in a barren land

plot and the inexistence of a museum display that would bring school children, local people, and tourists, there was no presence of the IIAM in the San Pedro cultural scene. Thus, the museum area created a showcasing space for the most emblematic materials and objects, which was inaugurated by the end of 2017. No human remains are included in this exhibit. Since then, primary and secondary school children, local community members, tourists, and researchers have been able to see and know about the fundamentals of the archaeological objects held at the museum. It was also available for the Andean School students.

During 2018, some strings to bring the museum project back to life started being pulled, and a productive and critical dialogue has just began between several stakeholders – Atacameño Peoples Council, IIAM, UCN, regional government, and municipality – addressing what kind of museum it should be, the types of community participation sought, and how will the stakeholders be articulated in the future management of the museum.

Final Words

The history of the museum of San Pedro de Atacama, located in the main town of the Atacameño people, is closely related to the history of this indigenous community. We cannot talk about this museum without mentioning its relations with the Atacameño people, which have been changing throughout their 60 years of coexistence and have fluctuated between relationships of denial, dialogue, negotiation, mediation, and collaboration. The different sociopolitical contexts experienced by Chilean society, in general, and indigenous people, in particular, have influenced the relationships between archaeologists from this museum and the Atacameño people.

Since the establishment of the Chilean multicultural state in the 1990s and the empowerment of indigenous peoples, the Atacameños stand out as one of the main stakeholders regarding the archaeological heritage in their territory. Disputes and conflicts between the museum and Atacameño leaders have become visible, and, despite the changes in this institution, different opinions and interests persist, although agreements have sometimes been reached as well as collaborative experiences. Depending on the context and the agents involved, certain events have triggered disputes, conflicts, and estrangements in the multicultural era. The most recent is the construction of the new museum, which evidences a historical dispute over control, custody, and rights over the archaeological heritage in San Pedro de Atacama. At the same time it shows the changing nature of Atacameño's heritage values, since the museum created by Le Paige, once considered for some indigenous leaders as the icon of a history of denial and domination, currently is valued by others as part of their history and heritage.

However, while the museum of San Pedro de Atacama has built new relationships with the Atacameños in the last 20 years and has marked a milestone in this field, asymmetries of power still exist based on the fact that Atacameño people are not fully integrated in decision-making processes. It remains to be seen if the organizational structure of the future museum will be able to critically and consciously address these power imbalances and move toward decolonizing and decolonized relationships.

Museum Security Network (MSN)

Mark Durney
Art Theft Central, New York, NY, USA

Basic Information

The Museum Security Network (MSN) is a Google Group listserv that keeps the public informed about the protection, preservation, and conservation of cultural heritage. The MSN was founded in 1996 by Ton Cremers, who served as head of security at the Rijksmuseum in Amsterdam, the Netherlands, from 1980 to 2003. Since 2003, Cremers has operated a museum security consulting company. In March 2010, Mark Durney, who operates Art Theft Central, a website providing news about and insights into art crime trends, began moderating the listserv. Jonathan Sazonoff has served as a contributing editor since 1997 and helped establish the MSN's multilingual scope.

The MSN's original aim was to serve as a source of information for cultural property protection professionals. Today, the MSN functions as a clearinghouse of information, and on a daily basis, Durney circulates online news articles, crime alerts, and subscribers' comments from around the world and in a variety of languages including English, French, Spanish, Italian, German, Dutch, and Mandarin via the listserv. Topics covered by its daily digest of information range from art theft to fakes and forgeries, from looted art and antiquities to conservation and restoration, from art vandalism and iconoclasm to restitution, as well as a number of other relevant issues. Its subscriber list has expanded since 1996 and now includes lawyers, security officials, museum professionals, conservators, academics, appraisers, art loss adjustors, insurers, galleries, dealers, auction

houses, and private investigators, among its 600 members. The breadth of topics and quality of information disseminated has enabled it to become an invaluable resource to so many people with a vested interest in cultural heritage.

Major Impact

Frequently, the MSN is the first to break news alerts related to stolen or looted cultural property. During Interpol's 6th International Symposium on Works of Art, Antiques, and Cultural Property at Lyon, France, in June 2005, a general secretariat delegate mentioned that he was first notified of a theft by the MSN, not by the member country/countries concerned (Interpol Minutes n.d.). The MSN's alerts have facilitated the recovery of stolen cultural property. In June 2006, 4 headrests and 2 Makonde masks were stolen in a daylight theft from the National Gallery in Harare, Zimbabwe. The director of the National Gallery, Doreen Sibanda, notified the MSN, local authorities, and Interpol in Lyon, France. In November 2006, an American collector of African antiquities contacted the MSN because someone based in Poland had offered him objects that closely resembled those published on the MSN. The seller, who was also discovered to be the thief, was later apprehended.

The MSN was also involved in a landmark First Amendment Internet legal ruling. In 2000, attorney Ellen Batzel sued Ton Cremers and her handyman Bob Smith for defamation after Cremers circulated a message authored by Smith on the listserv that claimed that Batzel was a descendant of a Nazi leader and that she harbored looted art from World War II in her home. Three years later, the Ninth Circuit Court of Appeals found that Cremers, who chose to post Smith's message on the listserv after reading it and making a few edits, was immune from liability under Section 230 of the Communications Decency Act of 1996 (CDA) so long as a reasonable person could conclude that the information provided by Smith was meant for publication on the Internet (Batzel v. Smith, 333 F.3d 1018, 1031 (9th Cir. 2003)).

The MSN is fully independent and refrains from any financial associations with commercial organizations active in the aforementioned fields. It is recognized as a cultural heritage resource by the United Nations Educational, Scientific and Cultural Organization (UNESCO), the International Criminal Police Organization (Interpol), the Federal Bureau of Investigation (FBI), the Smithsonian, and the Getty, among many other organizations. Over the past decade, the MSN representatives have been invited to meetings and conferences hosted by Interpol, the International Council of Museums (ICOM), UNESCO, and other cultural and educational institutions.

The MSN serves to establish qualitative data that generates awareness related to the realities of art crime. Due to the fact that art crimes are often underreported and misunderstood, the MSN seeks to collect and disseminate information that enables its readers to analyze the current trends and to develop new methods that help better preserve the cultural record.

Museums and Memory Experiences

Emma Waterton
Institute for Culture and Society, Western Sydney University, Penrith, NSW, Australia

Introduction

The study of "memory" has seen a steady proliferation across many humanities and social science disciplines dealing with the past, including archaeology, geography, history, heritage studies, anthropology, and museum studies. Here, it is stretched beyond a psychological interest in individual cognition to that of public or collective memory, which operates at a broader, communal level. One of the most obvious forums through which this type of remembering is engaged with is that of the museum, a cultural space that is today often referred to as a "site of memory" (Nora 1989) or a "memoryscape" (Edensor 2005). These sit alongside other socially and spatially produced sites of memory, such as memorial sites, war monuments, graffiti sites, plaques, and historic districts, all of which are public places onto which specific narratives about the past – official and otherwise – are etched. Whether literally or metaphorically, these places embody and speak of the past and, in so doing, push forward messages about identity and belonging in the present.

Numerous recent events have served as potent reminders of the power and politics of memory. Most visible here has been the removal of Confederate statues in the United States, particularly that of General Robert E Lee in Charlottesville, Virginia, in 2017, which triggered violent confrontations between those with opposing views on the past that statue embodied. Likewise, Australia has been embroiled in sustained public debate over a range of statues, memorials, and acts of commemoration that legitimize discourses of "discovery" and dispossession; in the United Kingdom, the "Rhodes must Fall" campaign similarly revolved around disputes about dissonant pasts and their protagonists. While these examples spill out beyond the walls of the museum (and thus the remit of this entry), they nonetheless amplify the importance of memory, and the work it does in wider society. They also point clearly to the power such memory has to breed rage, regret, and resentment, along with a host of other – both positive and negative – emotions.

Definition

The idea of "memory" that circulates within the museum setting is a peculiar one. Indeed, memory is able to permeate that cultural space despite the absence of both substance, in the sense of a "remembering subject," and physical organ – something that actually operates memory – such as the human brain (Weltzer 2010: 5). Rather than thinking in terms of individual memory, the museum context calls for a different sort of conceptualization – one that is cultural and social and thus one that exists *between* people and not exclusively *within* them (Weltzer 2010: 5). Here, it is comprised of shared meanings, narratives, and images that are compressed together into a useable past which can be "... harnessed for some purpose in the present" (Wertsch 2002: 31). As Jay Winter (2009: 252), a prominent scholar working in the field of remembrance, has argued, museums can thus be understood as physical "sites of memory," or those "places where groups of people engage in public activity through which they express 'a collective shared knowledge ... of the past, on which a group's sense of unity and individuality is based'" (Winter 2009: 252; see also Crane 2011; Dittmer and Waterton 2016).

Dealing as they do with collective memories, or that "... what remains of the past in the lived experience of groups" (Cubitt 2007: 10), museums are necessarily imbued with messages and meanings that are social in origin and embedded in a range of cultural and political contexts. The memories they trigger or produce are thus also inflected with, and influenced by, language, rituals, and commemorations, and perform in a variety of processes that make past events meaningful in the present. This type of memory is highly contested – as the examples with which

this entry opened illustrate – and draws implicitly upon notions of power; indeed, remembering in a museum setting is always selective and thus yields to particular versions of the past which prioritize certain actors at the expense of others. Of course, not all memory experiences occurring within the museum setting are the same. Rowe et al. (2002) have identified four key ways in which memory is utilized and/or engaged with in museums, all of which oscillate between "the museum" and "visitor" as producers of those memories. They begin with a memory experience that encourages visitors to tap into larger group narratives and make links with their own life stories; importantly, in these exchanges the larger narratives remain undisrupted, with individual memories simply rolled into them in order to give them meaning (Rowe et al. 2002). Their second form of memory experience likewise envisions an intersection of larger, official memories with personal ones, but here those personal memories are utilized in a bid to expand the relevance of the museum to a wider population. In other words, the personal stories of previously excluded groups are used as an "entry point" or guide for the co-opting of a broader range of participants into authorized narratives (Rowe et al. 2002). The third and fourth modes of memory associated with museums are geared around an assumption of active engagement on the part of museum visitors. In the first of these, museum visitors undertake what Rowe et al. (2002) label "poaching," a process in which the overarching narrative plays second fiddle to the more important personal memories – authorized narratives thus become those from which visitors seek to escape in order to enter a more intimate space of private remembering (Rowe et al. 2002: 106). These performances operate *outside* of the parameters set up by official memories. The final proposed way in which visitors may engage is via memory work that serves to furnish museum narratives with personal accounts that either support or deny their message. Rather than using the museum's cultural spaces to launch into their own memories, visitors draw those memories *into* the public narratives already on display. They become, as Rowe et al. (2002: 108) point out, "authorities in their own right who can testify as to the truth of the museum's representation." This is of course in no way an exhaustive list of the ways visitors experience memories within the museum setting, but it does serve as an indication of the nuanced ways in which such engagements may occur.

Key Issues/Current Debates

The memorialization of the history of enslavement and the trading of African people offers insight into the different, and often conflicting, ways that collective memories and recollections of the past can be evoked and experienced in the museum setting. In the UK, for example, the history of "abolition" has been retold and remembered in a number of exhibitions, through which museums have been transformed into either sites of resistance, memorials to suffering, or celebrations of individual heroism (for an expansion of this argument, see contributions in Smith et al. 2011 and their analyses of the bicentenary of the abolition of the transatlantic slave trade). As different interest groups and stakeholders undertake performances of remembering at the various museums dedicated to this theme, they rehearse and make new meanings for themselves in the present, often regarding issues of social justice, emancipation, or "race relations." Such themes have also been comprehensively explored in the American context by the geographer Derek Alderman, particularly the American South, whose work has challenged the racist narratives often brought to bear on the history of slavery at southern plantation museums (see Alderman et al. 2016; Alderman and Modlin 2016).

A second example can be drawn from the "history wars" surrounding the display of the cockpit and nose section of the *Enola Gay* in the proposed exhibition, "The Crossroads: The End of World War II, the Atomic Bomb, and the Origins of the Cold War," at the Smithsonian Air and Space Museum in Washington, DC (Wallace 1996). This is an example of a failed exhibition that has since become synonymous with debate due to the perceived threats it made to American collective memories and sense of "self." In the

proposed museum script, a challenging narrative was used to question the dropping of the atomic bomb on Hiroshima, a narrative that was vehemently opposed by a number of stakeholder groups, including US veterans. Embedded within the ensuing debate was a fear that creating such a critical memory space would unsettle broader, national memories of peace and heroism for museum visitors, triggering in their stead a newer memory laced with issues of guilt and culpability. Thus, perhaps more than any other in the field, the example of the failed *Enola Gay* exhibition captures the power of ideological messages implicit within the display of memory.

However, perhaps the most widely cited examples illustrating the relationship between museums and memory emerge from attempts to engage with the meaning of Holocaust remembrance. Indeed, the capacity of museums to adequately capture and represent the Holocaust has been a central debate within the museology literature for decades. This is because it stands in as a powerful example of how the past can be remembered differently by different individuals and communities. Levy and Sznaider (2002), for example, provide a thorough analysis of the disparate memory experiences encountered in Israel, Germany, and the USA, noting that the strategies of remembrance drawn upon in each country are inflected by the wants and demands of specific – and disparate – interest groups. For Israel, this has produced an ambivalence oscillating between silenced remembering and sacred remembrance (Levy and Sznaider 2002). In Germany, the immediate silences following the war have today been replaced with a critical and self-reflective narrative espoused in its national museums (Levy and Sznaider 2002), while the USA, by contrast, performs its own unique memorialization, referred to as the "Americanization of the Holocaust," a point evidenced by the sheer number of museums dedicated to its theme (Novick 1999; see also Young 1993). In all three contexts, museums have to flirt with, and respond to, a range of social and political tensions and match these against their own politics of display. As a consequence, the museum one chooses to visit – be it the Holocaust History Museum (Jerusalem), the Jewish Museum (Berlin), or the United States Holocaust Memorial Museum (Washington, DC), for example – mediates almost entirely the memory experiences that history has to offer.

The three museum experiences briefly described above are situated within a social context motivated by examinations of national guilt and apology, in which broader narratives of self and identity were – and continue to be – put at risk. In these scenarios, there has been a tendency to construct and use seemingly consensual narratives as something of a metaphoric screen (see Sturken 1991: 118). Such screen memories are granted the power to master the process of remembering for a whole range of subaltern and alternative groups, thus underscoring the political nature of memory both within museums and more generally. What this tells us is that the notion of memory can never be called upon to simply provide nostalgic and apolitical reflections of the past; rather it is itself a concept shot through with conflict as a range of memories work in tension with each other.

It also tells us that behind such screens lies a range of highly emotive and affective experiences. Thus, a more recent move in the literature has sought to bring the politics of affect and emotion to bear on the museum-memory nexus (see Gregory and Witcomb 2007; Witcomb 2014; Schorch et al. 2017; Tolia-Kelly 2017; Dittmer and Waterton 2017). This move is underpinned by the proposition that in order to engage positively in memory-work, museums need to retain currency, relevance, and continuing debate, as well as the ability to prompt a form of "critical learning" (Simon et al. 2000: 7; see also Cooke and Frieze 2017). Two case studies drawn from the Australian context speak to this idea: the Jewish Holocaust Centre and the Immigration Museum, both located in Melbourne. The former is the focus of recent work by Cooke and Frieze (2017), who have examined the role of survivor guides and eye-witness (oral and video) testimony in such exhibitions, the incorporation of which precipitates a range of emotional and bodily responses in visitors. Likewise, Philipp Schorch et al. (2017) have explored the notion of "affective cosmopolitanism" in the context of the

Immigration Museum, foregrounding, in particular, the emotional affordances of individual objects, photographs, and the faces and stories of tour guides. Importantly, they also point to the capacities of visitors to *be* affected.

This emerging interest in the academic literature in the way emotion and affect figures in the memory-work undertaken within the spaces of museums continues to grow. It brings with it an additional dimension to the museum-memory nexus and makes prominent the potential for affective-subjective dynamics within the museum setting, which in turn might trigger embodied engagements and acts of meaning-making.

Museums and the Distortion of Archaeology for Political Purposes

David Browman
Department of Anthropology, Washington University, St. Louis, MO, USA

Introduction

Museum interpretations of archaeological materials not surprisingly often reflect the general worldview of their audiences. Thus, during the late nineteenth and early twentieth centuries, various neophyte American museums developed exhibits that highlighted local prehistoric cultural origin explanations from racist perspectives or from "fantastic archaeology" perspectives. Often, these two approaches were combined, with museums arguing that the indigenous Americanist populations could not possibly have created the local archaeological sites and artifacts, based on perceptions from racial stereotypes. Rather, the curators looked to settings like Atlantis or Mu or to voyagers from Old World civilizations to produce these cultural manifestations, which they believed spread in successive waves via diffusion. These interpretations then served to reinforce local political agendas for paternalism, peonage, and slavery.

By the second half of the twentieth century, due to methodological advances such as radiocarbon assays and trace element analyses, the common political uses of archaeological museum materials had changed.Cultural-historical explanations replaced diffusionism. With the consolidation of U.S. scientific hegemony over countries in Latin America after WW II, there was essentially a type of cultural imperialism in place in interpretations. European philosophical "enlightenment" led exhibit preparators to feel that the use of logical positivism and empiricism, as employed in cultural processual studies, could definitively answer cultural evolutionary questions. There were continuing arguments whether museum curators should employ particularistic approaches; whether they should adhere to description only, just presenting a chronicle without implying causality; or whether they should employ generalizing perspectives, driven by processual or theoretical concepts.

The leading proponents of this processual approach were museum staff trained or influenced by European and U.S. institutions, who sought to create exhibits explaining materials in terms of social institutions. Prehistoric societies' features often were interpreted in terms of market forces, utilizing the parameters which shaped contemporary western economies. This practice developed into culture-ecological and neo-evolutionary models in the 1960s and 1970s, with a further subsequent shift from cultural-historical reconstructions to ecological-systemic approaches. But at the same time some scholars began arguing for a more relativistic, post-processualist viewpoint. This latter framework focused on the historic actor and reminded the viewer that knowledge is socially constituted and additionally that museum agendas are conditioned by nationalistic goals.

Key Issues/Current Debates/Future Directions/Examples

In Latin America particularly, exegesis of regional museum trajectories shows that under the guise of promoting cultural patrimony, institutional displays have been much influenced by imperialism, colonialism, and nationalism. Prehistoric cultural models that national museums have supported have changed with respect to the intended audience. U.S. cultural imperialism, manifested through its museum and research personnel essentially appropriating and manipulating viewpoints relevant to zonal archaeological resources, ignored the native peoples' own traditional perceptions. There is an active dialectical discussion between the non-indigenous primarily Euro-American populations, for whom the indigenous prehistoric patrimony is often mainly academic, and the First Nations groups, for whom museum studies are on one hand a study of their ancestral

heritage but on the other hand often a direct challenge to their own cultural narratives.

An excellent example of national governmental involvement in museum archaeology can be seen in Bolivia. A focus on the importance of archaeological Tiwanaku to the national patrimony was emphasized from the beginning of the twentieth century, with the most popular models arguing for its genesis from "lost Atlantis." But by mid-century, the local Aymara people were seen as progenitors, and with the Bolivian MNR revolution of 1952, it was decided to make Tiwanaku a fundamental part of state indigenismo policies. The restoration process and development of a major museum for the site was a political decision, the funding based on restoring the site to its presumed original glory to serve as a "sacred" political ancestral place for the country, the focal point of the national cultural patrimony. Moreover, a concern for the physical preservation of the national cultural heritage from the site was pursued by museum personnel. Foreign researchers had been siphoning off the finest and best of the Bolivian national heritage to European and North American museums. Hence, at the same time that state museum workers were instrumental in creating legislation to glorify Tiwanaku as the origin of high Andean culture, ancestral to the Incas, they simultaneously labored to make it illegal to export any further patrimonial cultural materials.

Museum positions in most of the American republics are still very much an upper-middle class career, and museum staffs are unconsciously (usually but sometimes overtly) influenced by cultural goals of their economic class. And because funding for archaeological cultural studies in several Latin American republics has been primarily controlled by the respective governments, national agencies tended to keep a tight control of dissemination and interpretation of the resulting data and often did not allow the publication or display of dissonant findings that did not support the current regime's agenda. The local archaeological reconstructions often became microcosms of the larger agendas influencing the politics of the world; for example, U.S. trained archaeologists often unconsciously imposed capitalistic models on the evidence, based on their own situations.

The domination of capitalist (and now neoliberal) economic philosophy from the North led various Latin American archaeologists, who often found Marxist perspectives more intellectually congenial, to call for a restructuring of archaeological interpretations in museums. Peruvian personnel initiated a new research agenda, termed "social archaeology," which spread throughout Latin America. For them, society was defined by its productive forms; hence, they argued that museum exhibits should no longer be based upon traditional stylistic or chronological criteria but on productive features.

This agenda led to the founding of the "Latin American Social Archaeology School" at a meeting in Teotihuacan, Mexico, in 1975. Participants explored many of these Marxist interpretations, deciding to develop a political approach for studying Latin American archaeology and for explaining prehistory to museum patrons, based on what they viewed as non-imperialist/non-bourgeoisie procedures. They set out arguments for what portions of the classic Marxist evolutionary model could be imported into Latin American interpretations and which ones were inappropriate, adopting a program which eschewed dogmatic Marxism, strongly rejected French structural Marxism, modified the approach to the study of modes of production through including the influence of culture, and advocated the use of the social practice of museum archaeology as a tool with which to fight for oppressed indigenous peoples' rights.

The "social archaeology" paradigm as well argued that national political agendas always influenced the actual practice of archaeology, and therefore, museum archaeology should explicitly become a part of such political agendas. It also contended that the indigenous peoples had spent millennia in discovering the optimum method of exploitation of the American environment, while the present Euro-American neoliberalism methods were resulting in the destruction of the environment, desertification, and other ecological disasters. Thus, its adherents argued that

the indigenous population had been disenfranchised, without its own cultural patrimony intact, and the Eurasian and African immigrant populations were also being denied access to a native patrimony that they did not know they had, because the previous intellectual perspective was unworkable. Hence, they proposed that museums should employ "social archaeology" practice as one political vehicle by which both the First Nations and the modern nation-states incorporating them might reclaim their appropriate patrimony.

The synopsis of changing viewpoints for interpreting the corpus of archaeological materials included within museum exhibits makes it clear that elucidating the past has been sociologically determined and not determined by dispassionate scientific rationality.

Museums of Brazil

Silvia Reis[1] and Alejandra Saladino[2]

[1]Museu Nacional, Universidade Federal do Rio de Janeiro, Rio de Janeiro, NJ, Brazil

[2]Federal University of the State of Rio de Janeiro, Rio de Janeiro, RJ, Brazil

State of Knowledge and Current Debates

The history of museums in Brazil reflects the different policies of colonization, conquering of territories, and creation of imperial and national discourses. From museums and research institutions founded to study and collect materials for the metropolis to museums created for a new discourse of nation (in the twentieth century) or as cultural commodities, legitimating narratives and subaltern memories, eclipsed by historical memory and official discourse, the museums of Brazil are instruments of negotiation of identities and social policies.

The history of museums in Brazil begins in the eighteenth century. In the city of Recife, it is possible to identify the first collecting experiences at the Vrijburg Palace (completed in 1642, during the rule of Mauritius of Nassau, during the Dutch occupation), in the form of a botanical garden, a zoo, and a curiosity cabinet, known as "Count's Office" (Gabinete do Conde) or "Natural History Museum" (Almeida et al. 2011). In the city of Rio de Janeiro, in 1784, Viceroy D. Luiz de Vasconcellos e Sousa, Count of Figueró, created the Casa de História Natural (House of Natural History), also known popularly as Casa dos Pássaros (House of Birds), for its main collection of stuffed birds. Francisco Xavier Cardoso Caldeira (also known as Francisco Xavier

Cardoso dos Pássaros) was responsible for its maintenance until his death in 1810. Luis Antonio da Costa Barradas became the second and last responsible for this institution, as it was closed in 1813. Its main purpose was to collect and prepare faunal specimens, sending them alive or stuffed to Lisbon, capital of the Portuguese Monarchy, upon request, and stand as a somewhat cabinet of curiosities.

According to D'Almeida (2015), the end of Casa dos Pássaros might have been caused by a disinterest of Count of Resende, successor of Count of Figueró, which led to abandonment and closing of its activities after the death of Francisco Xavier Cardoso. In 1813, Casa dos Pássaros was formally extinguished by Prince Regent D. João VI. Its collections were transferred to the Academia Real Militar (Royal Military Academy), where some of it was lost without conservation.

In 1818, D. João VI founded, in the capital of the then Viceroyalty, the Museu Real (Royal Museum), as part of the many institutions created to accommodate the transfer of the court to the colony (Brasil 1818; Museu Real n.d.). Located in the downtown area of Rio de Janeiro, the Museu Real (renamed as Museu Imperial e Nacional in 1824, and as Museu Nacional in 1890) was transferred in 1892 to the former residence of D. Pedro II, ousted emperor in 1890, after the proclamation of the new republican regime. The palace, located in Quinta da Boa Vista Park, houses collections of anthropology, archaeology, ethnology, linguistic (mainly records and studies about indigenous languages), botany, zoology, geology, and paleontology.

At first, as a colony and during the monarchy, Museu Nacional was the central institution representing and showcasing natural and cultural goods from the Brazilian territory. The main objective stipulated in its foundation decree was to "promote the knowledge and studies of natural Sciences in the Kingdom of Brazil," to analyze what could be applied in the industry, commerce, and arts (Brasil 1818).

The product of expeditions conducted by naturalists and findings made by particulars were sent to Museu Nacional. This focus on scientific expeditions, in a Natural History perspective, researching, cataloguing, and collecting samples of natural materials and local species, was the base for creating other museums of Natural History through the nineteenth century, reflecting regions of interest, such as listed in Fig. 1.

Name	Created in	Location	Current affiliation
Museu Real (Royal Museum, currently known as Museu Nacional, National Museum)	1818	Rio de Janeiro, state of Rio de Janeiro Southeast Region	Federal University of Rio de Janeiro
Gabinete de História Natural do Maranhão (Natural History Cabinet of Maranhão)	1844	state of Maranhão North Region	extinguished in date unknown
Museu Paraense (currently known as Museu Paraense Emílio Goeldi)	1866	Belém, state of Pará North Region	Ministry of Science, Technology, Innovation and Communication
Museu Paranaense	1876	Curitiba, state of Paraná South Region	State of Paraná (since 1882. Created as a private museum)
Museu Botânico do Amazonas (Botanical Museum of Amazonas)	1883	Manaus, state of Amazonas North Region	Closed in 1890 (created as an imperial museum)
Museu Paulista	1894	São Paulo, state of São Paulo Southeast Region	São Paulo University (a state university)

Museums of Brazil, Fig. 1 Natural History museums created in the nineteenth century

The Ancient Egypt and Greco-Roman collections housed in Museu Nacional were acquired through the royal family, as the former was brought in 1844 by D. Pedro I, and the latter brought by Empress Teresa Cristina, wife of D. Pedro II, in 1853. Therefore, Museu Nacional reflects different interests, from state policies to what the royal family envisioned for a national and imperial museum, having European museums as an inspiration to be followed (Schwarcz and Dantas 2008; Santos 2000, 2015).

The Exposição Anthropologica Brasileira of 1882 (Brazilian Anthropological Exhibition) at the Museu Nacional was marketed as the first exhibition about Brazilian anthropology, with material culture and human remains from indigenous people, from their own collections and other institutions, such as the ceramic artifacts of Marajoara Culture, part of the collection of the Museu Paraense Emilio Goeldi, another very important museum for the development of science and the preservation of the country's cultural heritage, located in the state of Pará, northern Brazil. Exhibition rooms were named after famous naturalists and historical characters, such as Lund Room (Peter Lund) with human remains, and Anchieta Room (Jesuit missionary José de Anchieta) with assorted photos and paintings of indigenous people from different authors, and with a copy of Anchieta's first grammar of the Tupy language (Museu Nacional 1882a, b). In a bid to place the Brazilian national museum as an equal within the international museum scenario, the exhibition portrayed a narrative about a rich past of the Brazilian territory, and the indigenous people as remnants of such past. The exhibition reflected the state policies of forced settlements based on race hierarchy and classification of indigenous people as primitive and needing to be "civilized" (Agostinho 2017; Reis 2016).

Most debates about history and geography occurred within the historical institutes, such as Instituto Histórico Geográfico Brasileiro (IHGB, Brazilian Geographical Historical Institute, founded in 1838 in Rio de Janeiro/Capital) and regional institutes as Instituto Histórico e Geográfico de Pernambuco (created in 1862) and Instituto Histórico e Geográfico de Alagoas (created in 1869). The Museu Paulista (São Paulo), created in 1895 as a museum of Natural History, became a symbol of national history, as it was installed in monument-building commemorating the independence of Brazil, the Monumento do Ipiranga, planned since 1824 and built from 1885 to 1890 (Moraes 2008).

In 1922, given the demand by intellectuals for a museum dedicated to national history, president Epitácio Pessoa created the Museu Histórico Nacional (National Historical Museum), in downtown Rio de Janeiro (still the Capital at that time). Museu Histórico Nacional was the first Brazilian college of museology and currently is part of the Instituto Brasileiro de Museus, IBRAM (Guedes 2010). Museu Nacional became part of the Universidade Federal do Rio de Janeiro in 1946, while Museu Paulista became part of the Universidade de São Paulo in a process initiated in 1934 and completed in 1963. From 1934 to 1963, different departments, such as zoology were transferred to USP, leaving Museu Paulista as a museum of history, ethnography, and archaeology. In 1989, archaeological and anthropological collections were transferred to the Museu de Arqueologia e Etnologia (Archaeology and Ethnology Museum, created in 1964), also part of USP, becoming a museum focused on historical collections about São Paulo (Ornstein and Barbuy 2015).

The Museu de Arqueologia e Etnologia of USP was created as Museu de Arte e Arqueologia (Museum of Art and Archaeology) to house classical collections donated along the 1960s from Italy, Chipre, and Portugal. At the same time, efforts to also represent the Brazilian society, African and African-Brazilian ethnographic collections, Pre-Columbian archaeological collections were added to the museum. Therefore, in 1972, the museum was renamed as MAE, reflecting its research focus and collections (Fleming and Florenzano 2011).

Regarding governmental agencies and policies of protection and regulation of cultural heritage and museums, in 1937, through law number 378, the Serviço do Patrimônio Histórico e Artístico Nacional (SPHAN, Service of Historical and Artistic Heritage) was created to promote the

conservation, register, and knowledge of national historical and artistic heritage (Rezende et al. 2015a). From archaeological sites to historical buildings, the SPHAN was responsible of registering all cultural heritage, mobile and immobile, and substituting the extinguished Conselho Nacional de Belas Artes (National Council of Fine Arts).

In 1946, SPHAN was changed to DPHAN, Diretoria do Patrimônio Histórico e Artístico Nacional (Historical and Artistic Heritage Directory), through the decree 8534, which also detailed its attributions and responsibilities. Beyond protection, conservation, and registering, DPHAN became responsible to oversee artistic and antiquities trade, coordinate federal museums under its subordination, advise other museums, and promote and guide the creation of museums of arts, history, ethnography, and archaeology (Brasil 1946; Rezende et al. 2015b).

With the reorganization of Ministério da Educação e Cultura (Education and Culture Ministry) in 1970, DPHAN was changed to IPHAN, Instituto do Patrimônio Histórico e Artístico Nacional (Historical and Artistic Heritage Institute). In 1976, a new regiment was published (Portaria MEC n°. 230), adding new departments within the institute, such as Divisão de Museus e de Difusão Cultural (Division of Museums and Cultural Diffusion) and Divisão de Arqueologia (Division of Archaeology). In 1979, IPHAN became a secretary superior to the Ministry of Education and Culture, renamed as Secretaria do Patrimônio Histórico e Artístico Nacional (SPHAN, Secretary of Historical and Artistic Heritage) as a result of the incorporation of the National Center for Cultural Reference (CNRC) and the Historical Cities Program (PCH) and the operation alongside the National Pro-Memory Foundation, resulting in the optimization and dynamization of actions in favor of Brazilian cultural heritage. From 1990 through 1994, in the middle of a political crisis, MEC and some cultural foundations were closed, while IPHAN was renamed as IPBC, Instituto Brasileiro do Patrimônio Cultural (Brazilian Institute of Cultural Heritage). The institute became known again as IPHAN in 1994, after a series of manifestations against the name IBPC. Currently, IPHAN is a government autarchy under the Ministry of Citizenship (Rezende et al. 2015b, c).

Nevertheless, in 2009, IBRAM, Instituto Brasileiro de Museus (Brazilian Institute of Museums) was created as an autarchy under the Ministry of Culture (Brasil 2013). All attributions regarding museums were transferred from IPHAN to IBRAM, being responsible for ensuring and implementing the National Museum Policy (PNM), created in 2003, among other duties and competences (Art. 3 and 4 of Law No. 11.906/09), while also being directly responsible for 30 museums, formerly under IPHAN management (Silva 2015). Therefore, museums with archaeological collections and cultural heritage must follow policies and answer to both IPHAN and IBRAM, since the archaeological heritage, as assets of the Union, is under the tutelage of IPHAN.

The number of museums in the twentieth century grew exponentially. In 1953, Heloísa Alberto Torres, director of the National Museum, organized and published Museums of Brazil, listing 175 museums, with names, addresses, and short descriptions. In 1973 and 1978, two editions of Guia dos Museus do Brasil (Guide of Museums of Brazil) were published, listing respectively 399 and 401 museums. Different methods of identifying museological institutions are also one of the reasons for fluctuation of total number of Brazilian museums. In 1983 and 1986, the Catálogo dos Museus do Brasil (Catalog of Museums of Brazil) listed 926 and 1158 institutions, while Guia de Museus Brasileiros (Guide of Museums of Brazil), organized based on CAMUS (Base de Dados de Museus Brasileiros/Database of Brazilian Museums, since 1993, at São Paulo University), listed in 1997 and 2000 only 755 and 529 institutions (Santos et al. 1984; Universidade de São Paulo 1997, 2000; Instituto Brasileiro de Museus 2011a).

In 2011, the Guia dos Museus Brasileiros (Guide of Brazilian Museums), published by Instituto Brasileiro de Museus (Brazilian Institute of Museums), presented a list of 3025 museums, with information such as address, date of creation, actual state, and type of

collections. The online version of Guia is divided in six volumes, covering museums in each one of the five regions of Brazil plus one volume dedicated to extinguished, renamed, or assimilated museums, virtual museums, and museums still being implemented.

In December 2015, the Rede Nacional de Identificação de Museus (ReNIM, National Network of Museum Identification) and the online platform Museusbr were launched, creating an accessible database for registering and updating information about new and current museums (IBRAM 2017). The Museusbr is open access and searchable (http://museus.cultura.gov.br/). The decree regulating ReNIM was published in January 9, 2017, having as obligatory members IBRAM and the Comitê Gestor do Sistema Brasileiro de Museus (SBM, Management Committee of the Brazilian System of Museums), and through membership of the state, district, or municipal systems of museums and state, district, or municipal public agencies (Brasil 2017). In 2017, over 3500 museums are registered and mapped in the Museusbr platform (Fig. 2).

The Cadastro Nacional de Museus has 11 categories regarding typology of collections: anthropology and ethnography, archaeology, visual arts, natural sciences and natural history, science and technology, history, image and sound, virtual, bibliothecographic, documental, archival. The last three categories distinguish, respectively, collections of printed materials; collections of manuscripts, printed, or digital materials organized under a specific theme; and collections of documents accumulated by a person or institutions throughout their career or history, as a product of their activities (IBRAM 2011b).

According to Bruno (2008, 2013/2014), the intense criticism of Brazilian museums through the twentieth century promoted profound changes to practices of collection, musealization, and meaning of cultural heritage. Social inclusion and participation have become key elements, especially in museums with ethnological and

Museums of Brazil, Fig. 2 Map of regions of Brazil, with the total number of museums per region

archaeological collections. Nevertheless, the decolonization of exhibitions and collection is an ongoing process, marked by two centuries of selective silencing and narratives. As Bruno analyzes (1999, 2013/2014), museums with archaeological collections deal with a so-called stratigraphy of abandonment, as colonial history was used for national narrative silencing precolonial and indigenous history. It is noteworthy that this *stratigraphy of abandonment* signals the secondary/eclipsed place that memories, heritages, and their narratives from the precolonial past still occupy both cultural heritage and formal school education.

Thus, in addition to the effects of the *stratigraphy of abandonment*, museums with archaeological collections face specific challenges related to the particularities of the management of archaeological materials (complicated by the increment of Contract Archeology, as the number of collections has increased exponentially in scale, a result of a developmental political-economic agenda) and the need to recognize its political dimension (Saladino 2015).

According to the decree n. 8.124, 17th October 2013 (subsection IX, chapter 1), regulating the Museums Statute (a Lei n° 11.904/09), a museum is:

> instituição sem fins lucrativos, de natureza cultural, que conserva, investiga, comunica, interpreta e expõe, para fins de preservação, estudo, pesquisa, educação, contemplação e turismo, conjuntos e coleções de valor histórico, artístico, científico, técnico ou de outra natureza cultural, abertos ao público, a serviço da sociedade e de seu desenvolvimento.

> a non-profit, cultural institution that preserves, investigates, communicates, interprets and exhibits, for the purpose of preservation, study, research, education, contemplation and tourism, series and collections of historical, artistic, scientific, technical or of other cultural nature value, open to the public, at the service of society and its development.

It is worth mentioning the consonance of the museum definition consolidated in public policies for the sector with the proposal by ICOM. However, it should be remembered that the diverse and distinct museum experiences developed around the world motivate a reflection on the purpose of the museum institution in the twenty-first century, beyond the administration of memory and preservation of its materiality, aiming to contribute to human dignity and social justice, assuming an inclusive and decolonial political stance.

Currently, the Brazilian museum diversity is noteworthy. Experiences and trajectories are markedly different, regardless of the management model adopted, some breaking with colonial logic, others radicalizing in decoloniality and others still following the Cartesian-scientist paradigm, aligned with the idea of the monopoly of truth attributed to modern science. It is worth noting that the rooting of the Social Museology paradigm enables several museum configurations, such as the community museums (as an illustration we highlight the Museu da Maré and the Favela Museum), the organic museums of the sertão of northeastern Brazil, and also the resignification of traditional museums, such as the Museum of Archeology and Ethnology at the University of São Paulo, which has been exhibiting collectively curated exhibitions with indigenous groups. This diversity was driven by the consolidation of public policies and their institutional instruments, funding and democratization, aligned with the notions of "heritage, social memory and museal processes in decolonial perspective" (Chagas 2017: 135).

The construction of the Museu do Amanhã (Museum of Tomorrow, inaugurated in December 2015) continues the trajectory of national narrative as spectacle, as an effort to place the nation as part of the international scene of (now postmodern) museums. Marketed as a legacy from the Marvelous Port project (a so-called reinvention of the port neighborhood), for the many international events such as the 2014 World Cup and the 2016 Olympic Games, it was an important element of a discourse of modernization and urban development of a notoriously decayed part of the center neighborhood of Rio de Janeiro. As a symbol of what should have been the revitalization of an historical neighborhood socially forgotten for so long, the Museu do Amanhã might represent the increasing social inequality of Brazilian society and the long-standing social debt. The narrative of progress stated in its name called attention

to the disregard for the existing museums and their collections lacking much needed support. Such urban revitalization proposal was nothing more than the same old story (Ferreira 2011; Bulcão 2017), a discourse of monumental constructions and ambitious look into a future, disconnected from our present and past.

Resulting from the same urban program linked to major sporting events held in Rio de Janeiro in the recent past, is the Museum of Removals, created by the activism and political positioning of a community removed from its territory. It is a museum that also deals with the possible future, but anchored in memories and a decolonial perspective.

However, political-economic reconfigurations have resulted in a weakening of policy effects, leading to weakening of key aspects such as budget allocation and other funding instruments, in addition to hiring specialists to renew staff. The progressive cut of funding and protection for historical buildings has deeper effects. Just in the last few years, different institutions suffered from uncontrollable fire. On December 21, 2015, the Museum of Portuguese Language was completely devastated, with only the building remaining. On September 2, 2018, the oldest museum of Brazil, the National Museum, suffered a fire that tore through all the collections housed in its main building, a royal palace over 200 years old. In fact, on June 6, the Museum had celebrated its 200 years anniversary. For decades the administration has sought funding for fire prevention, and to move all laboratories to another facility, aiming to keep the palace solely for exhibitions.

The public outcry for the tragedy of the National Museum added to encompassing sense of impotence felt by the Brazilian society. Different sectors are mobilizing to find ways to prevent another preventable and long announced tragedy. From universities, collaborative networks, IBRAM, IPHAN, and parliamentarians of the state of Rio de Janeiro, there is a general feeling of needed change. Nevertheless, the ongoing crisis in Brazil feeds into fallacious dissent over what matters most, if in a society plagued with such social inequality the reconstruction of a museum should take precedence over health and education.

Myanmar (Burma): Archaeological Heritage and Its Management

Bob Hudson
Archaeology Department, University of Sydney, Sydney, NSW, Australia

Introduction

Myanmar's predominantly Buddhist culture has a substantial archaeological heritage. Religious buildings, some dating back to the first millennium CE, number in the thousands. Many active Buddhist sites are managed by trustees,

sometimes with input from government authorities. Gazetted archaeological sites, such as Bagan with its more 3,300 buildings, are managed by the Department of Archaeology, National Museum and Library, which is a division of the Ministry of Culture. The ministry states in part that its mission is "to love and cherish the country and the people by taking pride in our traditions as well as by preserving, exposing and propagating Myanmar cultural heritage . . . to help develop unity, nationalistic spirit and patriotism among the people." The Archaeology Department employs conservators and engineers to maintain and repair buildings and their contents, as well as research officers, who conduct excavations.

Myanmar (Burma): Archaeological Heritage and Its Management, Fig. 1 Myanmar (Burma) and some of its main archaeological and cultural sites

Historical Background

Paleolithic to Early Urban

Myanmar (Fig. 1) has had human settlement dating back to between 55,000 and 70,000 years ago, when the dispersal of modern *homo sapiens* out of Africa brought about the occupation of the coast of the Arabian Peninsula, the river valleys of India and Burma, Island Southeast Asia, and Australia. In Myanmar, this population is still visible in Paleolithic tools that have been found across the Ayeyarwady Valley. Occupation of cave sites from around 10,000 years ago has been detected, with the gradual appearance of polished stone tools, incised pictographs, and ochre paintings.

Settlements from the Bronze Age (from around 1500 BCE) and the Iron Age (from 500 BCE) have been located in Upper Burma. By the middle of the first millennium BCE, the arrival of iron technology coincided with an expansion of personal wealth and clear evidence of social differentiation, notably in the Samon Valley and at Halin. Some skeletons from this period are found with armloads of bracelets, their clothing, and persons decorated with hundreds of beads. Burials include bronzes that probably come from southern China (Fig. 2), carnelian beads originally from India but quickly produced locally, and blue-green glass ornaments in styles also found as far away as Cambodia, all suggesting that goods and information travelled long distances over the trade routes of the time.

Migrants from the Samon Valley probably built, from around CE 200, huge walled cities at Pinle and Halin, north of the Samon, and Beikthano and Sriksetra, to the south. Brick construction, Indic deities, and cremation suggest that the indigenous leaders were enthusiastic adaptors of cultural notions from India. Known today as the Pyu (a name given to them by the Chinese), these people developed extensive rice agriculture in and around their cities. Their religion incorporated Buddhism, Hinduism, naga (snake/dragon) worship, and animism. Their settlements feature pots of cremated bones buried in or around brick shrines. The Pyu used coins (Fig. 3) which featured Indian-style symbols but no names or dates.

Myanmar (Burma): Archaeological Heritage and Its Management, Fig. 2 Bronze pull toy from a Samon Valley grave, probably traded from southern China

Myanmar (Burma): Archaeological Heritage and Its Management, Fig. 3 Indic symbols and Pyu rising sun design on a coin from Halin

A few words of the Pyu language have been translated from inscriptions, but they left behind few written records.

The dominance of the Pyu cities gradually faded away due to a combination of factors including siltation of their agricultural systems, a decline in the authority of the chiefly families and the intrusion, including slave raids, by Nanchao, a Tibeto-Burman-speaking principality in what is now Yunnan. The Pyu lands and cities were slowly incorporated into the Bagan kingdom. Halin had a governor appointed by Bagan in the eleventh century. There are records of princes of Bagan being given Sriksetra to "eat," which meant they were entitled to its revenues. The Shans (or Tai) arrived between the ninth and eleventh centuries and settled in the hills on the Thai-Burma border. The other major group was the Mon, who spoke a language in same family as Khmer and appeared to have migrated into southern Burma from the old Dvaravati kingdom in Thailand.

While the Pyu were active on the central plain, across the Arakan Yoma (mountain range) on the west coast were two contemporary and in many ways similar cities. Dhanyawadi (fourth to sixth centuries CE) and Vesali (fifth to eighth centuries CE) were also large sites enclosed by brick walls. These cities also used coins with Indian symbols. Artworks suggest a mixture of Buddhist and Hindu elements.

Bagan: Eleventh to Fourteenth Century CE

There is a substantial gap between the traditional history and the evidence of archaeology for the first millennium CE in Myanmar. We know from dates on burial urns, for example, that there was a royal dynasty at Sriksetra between CE 688 and 718. These were leaders whose names all ended in "vikrama," a Sanskrit title. Despite the Burmese chronicles' enthusiasm for listing royal dynasties, the "vikramas" are never mentioned. According to the traditional histories, a dynasty of kings ruled at Bagan from the first century CE, but there is little evidence to support this. We know, however, that pottery was being made at Bagan perhaps as early as CE 760. There are also temples, pottery, beads, and Buddhist artworks in the Pyu style at Bagan, suggesting that the site may have been settled during the second half of the first millennium.

Inscriptions at Bagan itself are known so far only from the early twelfth century, although some of these refer to earlier events. Bagan was the site of an artistic and building explosion from the eleventh century (Fig. 4), peaking with the construction of more than 2,500 religious structures in the thirteenth century. Early artisans may have arrived from India, as expanding Hindu and Moslem polities reduced the demand there for Buddhist art and architecture.

Myanmar (Burma): Archaeological Heritage and Its Management, Fig. 4 The Shwezigon Pagoda, Bagan

After 300 years of military domination and economic expansion, the Bagan kingdom was put under pressure by the Mongols in the late thirteenth century. The commitment of resources to religious buildings also appears to have overstretched the economy. The center of Burman government gradually moved north to the area around Mandalay and remained there for most of the time until colonization. The geopolitical contraction of Bagan was followed by an expansion of Mon polities in the south and the rise of Mrauk-U on the west coast.

Mrauk-U

During the Bagan period, a number of small principalities on the west coast, such as Sambawak, Launggret, and Parein, led fairly autonomous lives, despite occasional attempts by kings of Bagan to carry off the Mahamuni image, which was believed to be a life portrait of the Buddha. In the 1500s, King Min Bin employed Portuguese mercenaries to help fortify his city, train his army, and equip his fleet. Mrauk-U took advantage of Bengal's war with the Mughals to seize East Bengal, which it held as vassal for more than a century. Eventually the Burmese King Bodawpaya (1782–1819) conquered Mrauk-U. After centuries of trying, the Burmese removed the Mahamuni image to Mandalay. At the same time, the Burmese took several Khmer bronze statues, which had passed through several hands before reaching Mrauk-U. They are now in the Mahamuni pagoda compound in Mandalay.

Other Kingdoms

With the decline of Bagan, Central Myanmar split into small kingdoms, Burman, Mon and, Shan, which regularly fought each other. At times, Bagan was a staging post for armies moving north or south, and its vast treasures, buried inside pagodas as Buddhist offerings, were regularly pillaged. In the eighteenth century, the Burmese King Alaungpaya, a dominant military leader, founded the Konbaung Dynasty which ruled Burma from Arakan to Tenasserim. In 1767, Burmese troops besieged Ayutthaya, pillaged the city, and carried off many captives. Ayutthaya never recovered, and the Thais reestablished their capital in what is now Bangkok.

Colonial Period to Independence

Territorial conflicts between the British in India and local Burmese armies led to the first British-Burmese war in 1824. In a process of colonial annexation that took several decades, the British finally took over all of Burma in 1886. The Burmese king and his family were exiled to India, and the last Mughal emperor was exiled to Burma. His grave can be visited in Yangon.

Japanese forces entered Burma in 1941. The British, including many Indian troops and civilians, retreated to India, burning or scuttling the old

Irrawaddy Flotilla that had plied the "road to Mandalay" as they left. Some of these vessels have been rehabilitated and are functioning examples of the country's modern technological heritage.

Key Issues and Current Debates

Heritage Sites

Paleolithic implements have been found throughout Myanmar, at sites such as Magwe, Yenanchaung, and Chauk in Central Myanmar and along the river terraces of Ayeyarwaddy near Sale and Bagan-Nyaung U. Stone implements have also come from cave sites such as Pindaya, under what are now Buddhist shrines, and Padah-Lin, which like several other cave sites is protected as much by its remoteness as by official decree. The Archaeology Department maintains a list of sites and their locations, but they are rarely visited except for study purposes.

There are 16 officially gazetted Bronze and Iron Age sites, some of which have been excavated and published by a joint Myanmar-French team. Details of sites can be found on Archaeology Department websites. Rather than provide a URL that may become outdated, we suggest that interested parties search the internet using keywords such as *Myanmar*, *ministry*, and *culture*.

Seven sites are designated as "Pyu ancient cities." These are Beikthano, Sriksetra, Halin, Kyaikkatha, Wethali (Vesali), Pinle (Maingmaw), and Tagaung. Halin, whose history goes back at least 4,500 years to a Neolithic pottery production site, also has several Neolithic, Bronze, and Iron period excavations conserved under cover as site museums.

Thirty-three areas are named as cultural heritage zones. These are generally sites that feature Buddhist pagodas, monasteries, or major sculptures. They include Bagan, Bago, several pagodas in the Mandalay area, Sagaing (a huge monastic site on the west bank of the Irrawaddy from Mandalay), and cave sites including Kawgun, which contains ancient stone sculptures.

The Archaeology Department has a priority list of over 2,000 buildings with mural paintings, suffering from water leakage, the key factor in deterioration. There are more than 4,000 stone inscriptions, many housed locally in more than 50 storage sheds. Scholars occasionally obtain rubbings from these. The sheds are usually maintained by monasteries, villages, or pagoda committees. Other classes of object that are the focus of conservation are parabaiks (folded paper books), inscribed bronze bells, clay votive tablets, and palm-leaf manuscripts.

In 2011, conservation-repair-reconstruction schemes were active at Sriksetra (Thayekhittaya), Bagan, Halin, Inwa, Bago, Pakhangyi, Tagaung, and Mrauk-U. There was also a focus on the restoration of nineteenth-century wooden monasteries at Mandalay, Sagaing, Inwa, Sale, Salin, Legaing, Pakhangyi, and Pakhannge and repair of the wooden U Bein Bridge at Amarapura.

The Department of Archaeology, National Museum and Library maintain museums at 12 archaeological sites, with important collections at Bagan, Sriksetra (Hmawza), and Mrauk-U, as well as the National Museum in Yangon. There are many small museums in monasteries or local towns, under local control.

The Myanmar government has "spent a large amount of state budget for the national culture preservation" by building replica royal palaces at Bagan, Bago, Shwebo, and Mandalay, as a "symbol of success" and a "way of uplifting . . . the national prestige." In 2012 the nomination process for UNESCO World Heritage status was commenced for the Pyu Ancient Cities, Sriksetra, Beikthano and Halin.

Anthropoid Origins

The study of Myanmar's paleontological record was brought to attention worldwide in 1999 when anthropologist Gustaaf Houtman focused on a search for fossils, including early primates, in a critique of what he called "Myanmafication," an institutionalization of tradition for political purposes. In particular, he pointed to the substantial involvement of the military in the search in the mid-1990s for primate fossils around the Pondaung hills. The paleontological evidence supports the theory that East Asia, including

Myanmar, may have been the homeland of the first primates. However, Myanmar scholars have at times taken theory as fact, linking this directly to later human populations, as "proof" that "Myanmar's pre-history dates back 50 million years."

The Mon Paradigm

The first significant leader of the Bagan period is considered to be Anawrahta (r. 1044–1077), although his story is suffused with legend. He is credited with the construction of irrigation works at Kyaukse, after dreaming of three snakes (perhaps representing the major rivers) which he battled. Anawrahta is said to have conquered a Mon-Khmer-speaking kingdom at Thaton, southeast of the modern capital Yangon (Rangoon), taking captives, Buddhist scriptures, and a generally more advanced culture to Bagan. The standard histories of Burma accept the story of the Mon conquest as factual. Professor Michael Aung-Thwin has suggested that the story was made up several centuries after the alleged event and has been wrongly adopted as fact by modern historians. This debate continues at conferences and in print.

The Repair Program

In 1975, a severe earthquake damaged many buildings at Bagan. UNESCO became involved in reconstruction. Since 1994, repairs have largely been funded by donations raised locally – something seen by many as an act that acquires religious merit. International participants in the post-earthquake repairs remain concerned about the direction the donor program has taken and the quality of the work. A cultural heritage conference was told in 2007 that "the utilisation of new materials and the indiscriminate use of concrete have contributed to falsifying to a considerable extent the existing monuments . . . the recommendations of UNESCO for the conservation of the masonry works and the paintings with the drawing up of a master plan went unheeded." In defense of the repair programme, Culture Minister Win Sein had said in 2001 that the objectives had been to satisfy the donors, to retain the original workmanship and design, and to make the buildings last longer. "These are living religious monuments highly venerated and worshipped by Myanmar people" he said, "it is our national duty to preserve, strengthen and restore all the cultural heritage monuments of Bagan to last and exist forever."

Mytum, Harold

Alasdair Brooks
The Grand Egyptian Museum (GEM) Project, Hill International, Cairo, Egypt

Basic Biographical Information

Harold Mytum, an authority in the archaeology of early Christian Ireland, Iron Age Wales, and the mortuary monuments of the modern world, was born in 1955. Mytum's B.A. (1977) and M.A. (1981) were from Selwyn College, Cambridge, and his Doctorate (1984) from Keble College, Oxford; his doctoral dissertation topic was *Settlement and Economy in Early Christian Ireland*.

Before completing his Doctorate, Mytum was appointed James Knott Research Fellow in the Department of Archaeology at the University of Newcastle (1980–1982) and then Lecturer in Archaeology at the University of York (1982). He would remain at York for the next 25 years, serving as Head of Department between 1996 and 2001 and promoted to Reader in Archaeology in 1998; during his time at York, Mytum was instrumental in the growth of historical archaeology (in the American sense of the archaeology of the post-1500 period) within the department. Mytum left York in 2007 to become the Director of the Centre for Manx Studies within the University of Liverpool's School of Archaeology, Classics and Egyptology. He was a Council Member of the Society for Medieval Archaeology from 1988 to 1997 and was the Editor of the society's journal *Medieval Archaeology* from 1989 to 1997. Mytum has also been a Committee Member of the Society for Church Archaeology (2007–2008) and a Council Member of the Society for Post-Medieval Archaeology from 2011; he served as the latter's President from 2014 to 2017, subsequently serving a 3-year term as Vice President and demonstrating a keen interest in SPMA's history while holding these offices (e.g., Mytum 2016). Mytum was elected a Fellow of the Society of Antiquaries of London in 1987.

Major Accomplishments

Mytum's core research areas are diverse, and while there are arguably links between each of them (religion, particularly Christianity, linking his work in Ireland and postmedieval mortuary monuments; the late Iron Age and immediate post-Roman periods linking some of his work in Ireland, Wales, and the Isle of Man), the totality of his work offers no straightforward overall categorization, except perhaps in his willingness to apply theory-informed analysis to fields where theoretical approaches were previously often lacking and his geographical focus on the area bordering the Irish Sea. Mytum's book *The Origins of Early Christian Ireland* (Mytum 1992) was one of the first attempts to develop a theory-informed approach to the archaeology of early medieval Ireland. Initially criticized on publication for its overtly theoretical approach (e.g., Sharpe 1993), the book's subsequent standing has grown significantly as Irish archaeology has come to engage more deeply with theory.

In Wales, Mytum was the Director of the long-running Castell Henllys project at the namesake Iron Age and Romano-British hill fort in north Pembrokeshire (between Fishguard and Cardigan). This 20-year project ran from the

mid-1980s until the first decade of the twenty-first century (Mytum 2013). During this project's long life, Mytum developed a strong interest in experimental building reconstruction and public interpretation. The long-running training excavations at Castell Henllys, which encompassed Iron Age, Romano-British, and postmedieval sites, included students from the United Kingdom, Australia, Europe, and North America. Since becoming Director of the Centre for Manx Studies, Mytum has extended this research to the Isle of Man, so that his focus on the Iron Age and early medieval period now encompasses the entire Irish Sea region.

Since the early 1990s, Mytum has increasingly turned his attention toward the postmedieval period, with a particular focus on mortuary monuments and gravestones and latterly on the archaeology of internment and prisoner of war camps (e.g., Mytum 2017). Much of his work on mortuary monuments has focused on Wales and Ireland (e.g., Mytum 2002) but has also encompassed international comparative studies (Mytum 2006), guides to graveyard recording (Mytum 2000), and overviews of mortuary monuments and burial grounds (e.g., Mytum 2004). While Mytum has not been the only British archaeologist to study death and commemoration in this period, he has been at the forefront of a those seeking to not only make the British archaeology of postmedieval death and commemoration more theory aware but also to make British postmedieval archaeology more generally engaged with theory.

N

Nabta Playa: Agriculture and Domestication

Kathleen Nicoll
University of Utah, Salt Lake City, UT, USA

Introduction

Nabta Playa is an ancient ephemeral lake and prehistoric archaeological site located in southern Egypt (Wendorf and Schild 2001; Fig. 1). Although the modern Nabta region is barren and lacks surface water due to its extremely arid climate, there was enough rainfall during antiquity to support a shallow 1,500 km^2 lake and to sustain a savannah grassland and various human activities. Extensive excavations in the region of Nabta have yielded valuable insights regarding the local Late Stone Age – Neolithic culture – and the climate change that caused desertification in this part of Saharan North Africa during the Late Holocene (e.g., Wendorf and Schild 1980, 2001 and references therein).

Key Issues/Current Debates/Future Directions/Examples

The archaeological, paleobotanical, and paleontological records near Nabta enable reconstructions of the critical adaptations and transitions from foraging to food production, domestication, and the practice of animal husbandry (Close 1987). Sites in the area preserve prehistoric dwelling structures, storage pits, wells, and various artifacts preserved in stratified contexts, including characteristic tool assemblages and microliths, decorated pottery and plainware, grinding tablets, and ostrich eggshell beads. More than 100 published radiocarbon dates constrain the occupation during wet phases and the timing of intervening droughts when arid, harsh conditions caused abandonment (Nicoll 2001, 2004; Fig. 2). Interpretation of the material culture suggests that the Neolithic people at Nabta developed more elaborate traditions and practices with increasing social complexity over time (Close 1987; Wendorf and Schild 1998, 2001).

Activities at Nabta commenced around 11,000–9,300 cal BP. The people appear to have herded cattle, but there is intense debate about whether the *Bos* varieties discovered in the excavations were domesticated (Wendorf and Schild 2001). It has been proposed that Nabtans might have regarded their cattle as economic units of social status and prestige, like some modern pastoralists in Africa that herd animals for a regular supply of milk and blood (Close 1987). However, these assertions are speculative, and such ethnographic analogues may not be relevant for reconstructing the Neolithic.

Nabta Playa: Agriculture and Domestication, Fig. 2 Major variants (italicized) and cultural transitions described at Nabta Playa and the surrounding region, modified after Nicoll (2004, 2012) and references therein

A drought caused the desiccation of Nabta Playa after 9,300 cal BP and forced people to migrate to areas with more water, causing consequent population increases along the Nile River Valley and other areas (Nicoll 2012). The people returning to Nabta after 9,000 years ago established larger settlements in which the huts were arranged in straight lines, and large, walk-in water wells were dug. The numerous grinding stones around Nabta suggest that cereal foods were consumed. More than 20,000 carbonized plant remains from 127 species were recovered from the excavations, including 10 tree and shrub varieties that are common in the Sahel and require 100–200 mm of rainfall per year. Paleobotanical remains included a number of edible plant foods, including variants of wild millets, sorghum, legumes, tubers, and fruits. Preserved bones of small animals (e.g., hares and gazelles) near the dwellings indicate that meat was part of the local sustenance. By ~8,800 cal years ago (~7,800 BP, uncalibrated), pottery was produced locally (Wendorf and Schild 2001, and references therein).

Between 8,000 and 7,000 years ago, Nabta Playa became dry and was abandoned during two major drought periods bracketed by radiocarbon dates. As hyperarid conditions developed, the water table dropped, the savanna grassland diminished, and wind deflation intensified, creating impossible living conditions. The people returning to Nabta after these droughts abated forged a more complex and organized society. The archaeological remains suggest the Nabtans practiced a ritualistic belief system associated with livestock. Excavated items supporting this inference include sacrifices of young cows, and their burial in clay-lined and roofed chambers marked with overlying stone slabs. The inhabitants of Nabta also constructed ~25 complex building structures with surface and subterranean features, including storage pit chambers and a shaped stone that might possibly represent the oldest sculpture in this part of Egypt (Nicoll 2012 and references therein).

Another significant find in the Nabta region is a Late Neolithic cemetery. Excavators discovered more than thirty graves, containing the remains of 69 individuals in all. Some of the graves had multiple and symbolic burials, and there were also two secondary burials, in which the skeleton eye sockets were filled with teeth (Kobusiewicz et al. 2004). A series of furnished graves date to 6,400 and 6,000 uncalibrated radiocarbon years BP. Associated grave goods – including carnelian beads, shell bracelets, polished stones, pottery, ochre, needles, stone tools, and carved figures – demonstrate that the Nabtans had trade connections across the region. The interpretation that these people practiced transhumance is substantiated by the graves containing offerings of disarticulated cattle and caprovid (e.g., goat, sheep) bones. Some evidence dating to ~8,100 years ago suggests the domestication of larger animals, goats, and sheep and development of animal husbandry, but these are controversial interpretations (Wendorf and Schild 2001).

The Nabtans erected monuments and megaliths made of large stone slabs, and these are thought to be among the oldest ceremonial centers and astronomical calendars found in this part of Africa (Wendorf and Schild 2001). Many of these structures involve large worked stones known as stelae or tumuli and are arranged on the landscape as mounded complexes, bedrock carvings located below the ground surface, semicircles, and linear orientations. Within the monuments, butchered cattle, goats, and sheep bones have been found, and these are interpreted as animal offerings. One tumulus site dating 7,400 years ago contained sacrificial remains of a calf buried in an elaborate chamber covered with tree branches (Wendorf and Schild 2001).

As drought conditions worsened around Nabta, water sources dried up, and the grassland disappeared ~6,000 year BP; the area was inhospitable after 5,300 years ago (3,350 BCE). Around 4,780 BP, hyperaridity prevailed, and the Sahara became established. This profound environmental change precipitated migration – an "Exodus event" in which humans left desert locales for more reliable water sources. As the

Nabtan and desert peoples relocated, they inevitably contributed their own culture and beliefs to the birth of ancient Egyptian religion and the Pharaonic civilization, which was organized around irrigation agriculture within the overpopulated Nile River Valley (Nicoll 2004, 2012).

Naples, Byzantine Dukedom of (Centuries VI–IX)

Luca Bozzarello
Department of Humanities, University of Calabria, Arcavacata di Rende, Cosenza, Italy

State of Knowledge and Current Debates

The history of Naples can be written thanks to a large number of documents that were saved and

recopied across the sixteenth to nineteenth centuries by many erudite scholars of heraldry and antiquities. These people, in searching for the ancient splendor of Naples, wrote monumental books on their native city. Even if those books are often unreliable, they still allow us to use information in written and material sources which is otherwise lost. Bartolommeo Capasso (1815–1900) can be considered an heir but also a brilliant renewer of this long tradition. Between 1881 and 1892, he wrote three famous and essential books containing the whole *corpus* of sources concerning the Dukedom of Naples, titled *Monumenta ad Neapolitani Ducatus historiam pertinentia*, which data were finely organized and commented by Giovanni Cassandro in his *Il ducato bizantino* (1969), surely the most comprehensive research on the theme.

Over the last 30 years, the most interesting contributions concerning Naples in the High Medieval Ages have come from archaeology through new excavations or reinterpretations of old ones (i.e., new facts about the Neapolitan port, the coast of Campania, the episcopal area). This is why a partial reconsideration of the Byzantine ages in Naples, the weakest part of even the most detailed research on the Dukedom, seems to be necessary.

Political History

The Dukedom of Naples was a province of the Byzantine Empire between the sixth and twelfth centuries. When it was conquered by the Normans (1139–1140), the Dukedom's territory included only the city of Naples and its hinterland. The dominion, however, had acquired its political independence since the middle of the ninth century, when its formal dependency on Constantinople was preserved to legitimize the creation of a hereditary state (Gay 1980: 225).

Born as Greek Cumae's colony, the ancient Naples developed on two different sites: the former of Parthenope (eighth century B.C.), seated on Pizzofalcone Hill and the island of Megaris (also known as Macharis, *Insula maris* or *Insula Salvatoris*, a place once attached to the mainland, while nowadays it is occupied by Castel dell'Ovo); the latter of *Neapolis* (sixth century B.C.), located away from the coast on Parthenope's left side. About two centuries later, *Neapolis* moved under Roman political influence and jurisdiction. From the fourth century B.C. to 476 A.D., it was a Roman city. After the fall of the Roman Empire, it passed through the reigns of Odoacre (476–493) and Theodoric (493–526) and his successors, enjoying the favor of the Goth government.

Loyal to the Goths, Naples was conquered for the first time by the Byzantine army led by Belisarius in 536 (Proc. *Bell. Goth.* I, 8–10 = Haury and Wirth 1963). According to some sources, the Byzantine soldiers devastated the city and decimated the population. This could be the reason why Naples was repopulated by people coming from villages and cities of Southern Italy, Sicily, and Africa. Perhaps something similar happened then or later. In any case, this tradition cannot be entirely accepted because the sources related to the event are dated, unreliable, or partisan. Moreover the elements handed down by those sources seem to be *tòpoi* because they are often connected to other war events of Neapolitan medieval history (Duchesne 1886: 290; Land. Sag. *Hist. Rom.* XVIII, 15–16 = Crivellucci 1968: 45–46; Burgarella 1988: 319; *Cron. di Part.* 49–50 = Kelly 2011: 232–238). Around 543 the Byzantines lost Naples. The city was conquered by the new Goth King, Totila. Only at the end of the Gothic War, Naples passed again to the authority of Constantinople which organized Italy, the new province of the Empire, according to the *Pragmatica Sanctio pro petitione Vigilii* (554).

The Byzantine authority over the whole Italy ended around 568–571, when the Longobards occupied more than a half of its territory (Pavia, Spoleto, Benevento). This pushed the Byzantine Emperor Maurice (582–602) to rearrange the Empire's Western provinces. The traditional separation between military and civil powers imposed by Diocletian and Constantine (third–fourth centuries) – a formal principle until the time of Justinian (527–565), even if it was often not observed – was thereby replaced by a new administrative organization, the Exarchate, according to which the military power and its

official, the Exarch, were imposed on the apex. Around 584–591 the Exarchates of Italy and Africa were created: the former based in Ravenna and the latter in Carthage. The political map of Italy had been changed. Under the control of the Exarchate of Ravenna were organized a series of Dukedoms, including the one of Naples. Sicily and Sardinia were not part of this system, because the former was connected directly to Constantinople and the latter to the Exarchate of Africa (Diehl 1888: 3–79; Burgarella 1988: 273–280).

The *dux* or *magister militum* was imposed on the apex of local Dukedoms. At the beginning the *dux* was charged only with military power. During the first decades of the seventh century, the *dux* progressively gained both military and civil powers, replacing the civil governor, *iudex provinciae*, that was suppressed. The last *iudex* mentioned in a source (625–638) is the *iudex Campaniae* (Kehr 1935: (8) 420). An *officium* composed of a plethora of officers was also established, and among them were *tribuni* and *comites*; these military commanders were established in *castra* and *civitates* (Diehl 1888: 3–79). The Roman curial system on the other hand failed, even if some of its delegates are still mentioned in the seventh century. Many of the tasks that used to be managed by *curiales*, especially poverty support policies and tax collection, were mainly managed by the Roman Church and the different local dioceses (Bozzarello 2015: 47–65).

At the beginning of the Exarchate, local *duces*, and other local officers, were chosen by the Exarch. From the second half of the seventh century, instead, *basileus* replaced the Exarch by choosing himself the new *duces* or just confirming the election carried out by different local soldiers. Naples was the first province in which this new system was adopted. The *Dux* Basilius (661–666) was ordered or ratified by *Basileus* Constans II (641–668) from Constantinople (Fedele 1903: 567). This operation was part of the whole Italian province rearrangement policy managed by the Armenian Emperor during his long journey in Italy (663–668), where he introduced the elements on which the future *basileus* Justinian II (685–95; 702–711) and Leo III (717–741) built the Theme of Sicily (692–695) and adopted the fiscal reform (731/732). In the new system arranged by Constans II, Sicily became the center of the Southern Italian administration. From this time the ancient region *Brittiorum*, known nowadays as Calabria, and the actual Salento or Terra d'Otranto, the region known across Antiquity and Late Antiquity as Calabria, became closely connected to Sicily (Burgarella 1988: 301–304). No evidence can prove the same thing for Naples, which was probably connected to the island at a later time (692/695 or 751). In the Naples of Basilius, where Constans II was twice in 663, the *Basileus* allegedly established new Byzantine regular troops (Paul. Diac. *Hist. Lang.* V, 12 = Zanella and Luiselli 2014: 438) and introduced the Neapolitan Mint, which occasionally worked (Pavini Rosati 1982: 665).

The political significance of Naples, designed by Constans II, became more relevant under the reign of Leo III, who transformed it into an archiepiscopal and autocephaly city, independent from Rome. This gave it an important role in the rearranged policy of the Southern Italian ecclesiastical geography (Waitz 1878: 422). In this case, Naples' political survival was only guaranteed by Stephen II, duke (755–767/768) and then bishop (768–800). Who, following his strong and clever opponent, Arechis II of Benevento (758–787), supported an intelligent policy of variable alliances. Indeed, Stephen II confirmed the civil authority of Byzantium on Naples through the seizure of the pontifical *latifundia* there located and the ecclesiastic authority of Roman Church on Neapolitan diocese and its bishop through a strong latinization of civic spirituality (Waitz 1878: 425–427; Fedele 1903: 570).

Moreover Stephen, who had imposed as dukes his sons and his son-in-law, had tried to build a dynastic dominion, but his system collapsed a few years after his death. Only under the *Dux* Sergius (†864), this political system was finally imposed, and the problems related both to the right of succession and to its legitimacy were definitely solved (Waitz 1878: 431; Fedele 1903: 571).

Territory, Borders, *Castra*, and *Civitates*

After the Longobardic invasion of Benevento (570), the borders of the Byzantine Campania together with the Dukedom of Naples were established by Lago di Patria in the North and Sele river, near to Salerno, in the South. *Terra Laboris* or *Liburia*, Acerra, Nola, and Nocera were the Eastern borders of the Neapolitan dominion, while the islands of Ischia, Procida, Capri, and Nisida marked its maritime and Western borders. In 593–594 the Longobards took Capua and then Salerno in 640. Gaeta had gained its independence from Naples in the second half of the eighth century. That example was followed in the ninth century by Amalfi and Sorrento. Around the tenth–eleventh century, the Neapolitan Dukedom's borders were set not too far from its capital.

Naples was protected by its strong position, reinforced by powerful walls. Recent archaeological studies have shown the different building steps of the walls: built in fourth–fifth B.C., it was restored for the first time in the fourth–third century B.C. by doubling (Boetto et al. 2010: 115) and for the second time in 440 A.C. by Valentinian III, Augustus of the Western part of the Empire (*CIL* X 1485). This is the reason that Naples seemed to be and really was almost unassailable by the Byzantine soldiers led by Belisarius, who managed to enter into the city by passing through an aqueduct breach (Proc. *Bell. Goth.* I, 10 = Haury and Wirth 1963). In 543 Totila took Naples by starving the people. Because of fear that the Byzantines could try a new siege of Naples to reconquer such a strong emplacement, he demolished part of the city walls (Proc. *Bell. Goth.* III, 8; Haury and Wirth 1963).

According to a late version of events (ninth century), the city walls had been reinforced by Belisarius, who added seven magnificent towers. Then, under the authority of Narses (555–568), who ordered the extension of Naples toward the sea, walls were built as far as the coast, where he ordered a ship's storage area to be built (*Vita s. Athanasii* I, 15–18 = Vuolo 2001: 116–117). In my opinion, this version of events is partially reliable. During the whole of the Middle Ages, the Neapolitan city walls were far away from the coast. They were separated from the coast by another fortified area called *Castellione nobum*, probably built in the tenth century (Feniello 1991: 175–179). Building cities far away from the coast, however, was common for the Byzantines. For example, the anonymous military treatise known as *De re strategica* or *Peri strategikès* (Dennis 1985: 32–37), written in the sixth century, in its chapters concerning cities and building techniques, recommends to build city walls of about 4 m height, between 18 m and 62 m away from the coast. Therefore, in my opinion, the anonymous hagiographer wrongly ascribed to Narses the huge public building (=*firmissimum aedificium*) near the Neapolitan harbor and connected to commercial uses a building that, as archaeologists have shown, was built in the seventh century (Giampaola et al. 2005: 47–91; Giampaola and Carsana 2010: 119–132). The same hagiographer ascribed to Narses the introduction of the city customs in Naples: an office that is attested to in Naples by proofs dated not before 1018, even if it was created in the Byzantine Empire under Justinian (Capasso 1881–1892: (377) 235–236).

From the Late Antiquity, a period of decadence began for Puteoli. Its acropolis became smaller, and even its port, which had been prosperous and active for centuries, was inactive (Schmiedt 1978: 171–172; Varriale 2004: 299). According to Procopius (Proc. *Bell. Goth.* I, 11 = Haury and Wirth 1963), during the Gothic War, Naples and Cumae were the only two fortified towns in Campania, and both were controlled by Byzantine garrisons. As well as Naples, after 543, even Cumae felt under Gothic control. Toward the last years of the war, the *castrum* was chosen by Aligern, Teia's brother, and his soldiers as a safe shelter for the royal treasure. Seated along Campania's coast on a step hill, Cumae had powerful walls and a strong geographical position (Agathias *Hist.* I, 8 = Keydell 1967: 19–20). That is the reason why Cumae was inviolable for the Byzantines, even when they demolished the Southern side of the walls, and Narses could gain the *castrum* only because Teia voluntarily surrendered.

It is highly probable that Narses ordered the fortifications to be rebuilt when the war ended. Recent archaeological excavations have shown

that during the sixth–seventh centuries, Cumae was an important Byzantine military base, almost abandoned by the civilian population (Caputo et al. 2012: 103–119). The partial depopulation of Cumae (Greg. Mag. *Reg. Epist.* IX, 143 = Recchia 1996–1999: 320–323) is allegedly the reason that Gregory the Great (590–604) ordered that his diocese be joined to Miseno in 592 (Greg. Mag. *Reg. Epist.* II, 37 = Recchia 1996–1999: 328–331). The independence of the diocese of Cumae was not restored before 649 (Kehr 1935: 469), and it is allegedly related to a steady rebirth of its civic life.

The strong maritime position of Cumae should be the reason it was invaded by the Longobardic troops of Romualdo II of Benevento (716/717), who were looking for a maritime passageway. The Longobard seizure was short. The reaction of the Neapolitans was almost immediate, and Cumae was reconquered by the *Dux* John (711–719), who was richly funded by the Roman Church with 70 pounds of gold (Paul. Diac. *Hist. Lang.*, VI, 40 = Zanella and Luisella 2014: 524–527; Duchesne 1886: 400–401; Waitz 1878: 422; Kehr 1935: (1–2) 471). This military operation was probably necessary because of the failure of a previous military operation by the Byzantine Navy led by Conon, the future *Basileus* Leo III, who, according to some isolated Eastern sources, had been in Campania in 715–717 (Gero 1973: 30; Burgarella 1988: 317–318).

Cumae was sacked by the Saracens in 915 and then definitively destroyed by the Neapolitans in 1207. The diocese of Cumae was divided between Naples and Aversa (Vitolo 1990: 79).

Connected to Cumae is the history of the close *castrum* of Miseno. Ruled by a Byzantine *comes*, Miseno had been fortified before November 589, but the *castrum* already needed to be restored in 599 (Greg. Mag. *Reg. Epist.* IX, 53; IX, 65; IX, 122 = Recchia 1996–1999: 182–185, 198–199, 286–287). In this case, the building expenses were partially supported by the Roman Church, who were concerned with protecting both the local bishop and the rich part of *Patrimonium sancti Petri* located between Cape Miseno and Nisida. Miseno, moreover, seemed to be really important for the Papacy, because this port was on the maritime route which linked Rome to Sicily, the pontifical granary (Greg. Mag. *Reg. Epist.* IX, 145 = Recchia 1996–1999: 322–325). As new archaeological studies have recently confirmed, at that time Miseno was an important economic center, which can be described as a manufacturing and exporting site (De Rossi et al. 2010: 487–495). The history of Miseno ended in 846, when it was destroyed by the Saracens. From that time its diocese was joined to the Naples diocese (Waitz 1878: 432–434).

During the High Middle Ages, the area Cumae-Miseno was Naples' maritime and land route to Rome. The main reason for this strategical arrangement was related to the Longobardic invasion of Capua, a city in which several Roman streets had their junction. Naples moved to Cumae-Miseno the ancient functions of Capua. This has recently been confirmed by archaeological studies, which have shown how this area was closely connected to Naples in the seventh century, in particular to its port through the Roman via *per cryptam*, a street that had been modified in order to respond to the new economic needs of medieval mobility (Giampaola et al. 2005: 47–91; Giampaola and Carsana 2010: 119–132).

Concerning the minor Neapolitan *castra*, mention should be made of the small *castrum* or *castellum Lucullanum*, which nowadays corresponds to the area between Municipio Square, Pizzofalcone, and Castel dell'Ovo. This place took its name from the Roman Senator Lucius Licinius Lucullus, owner of a magnificent residence located in the area which was turned into an imperial residence later on. *Castrum* was only built in the fifth century. Here in 476 the last Roman Emperor Romulus Augustulus was exiled with a considerable 6000 *nomìsmata* or *solidi* revenue. Here, some years later (492–495/496), the exile Saint Severinus' (†482) monastic community (Eugippius *Vita sancti Severini* 46, 1–6 = Genovese 2012: 128–131) was welcomed in grand style by the Neapolitans. The community was settled in the Monastery of St. Severinus in *Lucullanum*, one of the biggest cultural centers of the Middle Ages, famous all over Europe for both the Saint's relics and its active *scriptorium* (Bozzarello 2015: 61).

During the Middle Ages, the *castrum Lucullanum* was mainly characterized by monastic settlements. Most of the monks here were cenobites, who lived in a monastery. A few hermits lived in the *castrum* as well, but during the ninth century, they became cenobites under Saint Bishop Athanasius I (849–872), who organized them in the new Monastery of St. Salvatore *in Insula maris* (*Vita s. Athanasii* IV, 35–40 = Vuolo 2001: 128–129).

In September 902 the Neapolitan authorities, *Dux* Gregory IV (989–915) and Bishop Stephen III (898–906), ordered the demolition of the *castrum*, already almost uninhabited, because they feared that the Muslim invaders, led by the Emir of Ifriqiya Ibrâhîm II ibn Ahmad, wanted to capture the place in order to turn it into a strategical base to attack Naples (Capasso 1881–1892: (1) 1–4). The military aspects of this operation were useless because the Muslim invasion was stopped by the death by dysentery of the Emir at Cosenza in October 902, and the soldiers left Southern Italy in retreat (Talbi 1966: 526–530). The few inhabitants of *castrum*, mainly monks, had already been moved into Naples, where they would have been well defended by the strong city walls. Therefore the old Monastery of St. Severinus *in Lucullanum* was abandoned, and its monks were moved into the Monastery of St. Severinus *in vico Missi*, then known as Monastery of Sts. Severinus and Sosius (about 930) and nowadays the location of the Public Archives of Naples (Capasso 1881–1892: (1) 1–4, 169; Kehr 1935: 457–459).

Despite its destruction, however, the *castrum* was not totally abandoned. Documents attest to some inhabitants in the tenth century and afterward. For example, the presence of some monks living in the *Insula Salvatoris* in the tenth century has been documented (Pertz 1848: 344). It's highly probable that the source refers to the Monastery of St. Salvatore *in Insula maris*, where some monks lived until 1132 before moving to other places (Kehr 1935: 462). But these are isolated proofs. From the tenth century, the *castrum* was mainly managed by some Neapolitan monasteries as an economic district, in which especially fishing was developed.

Ports

The port of Miseno, an ex Roman Navy port, during the Late Antiquity, was well connected to Rome. Cumae and Puteoli were totally or partially inactive during the same age. In the maritime Neapolitan system, the other minor ports, for example, Nisida (located near Miseno), Castellammare di Stabia, and Sorrento, had little importance. The main ports in Campania were Amalfi (ninth–tenth centuries) and Salernum (tenth–eleventh centuries, which had almost a monopoly over the Mediterranean trade; but at the time of their power, these ports were already not included in the Neapolitan borders.

The golden age of the port of Naples began under the Norman Kingdom. Its port, however, was active and important even in the High Middle Ages, and it was well connected to the East, especially to Alexandria (Greg. Mag. *Reg. Epist.* X, 21 = Recchia 1996–1999: 566–573).

Since the sixteenth century, Neapolitan erudites and historians have been involved in searching its locality, but only in the nineteen century, the first well-founded but partial hypotheses on this issue were provided by some scholars. New archaeological studies, related to excavations carried out on the Underground Line 1 area, have shown that, between the centuries fourth and third B.C. and fifth A.C., the port of *Neapolis* was located in today's Municipio Square. This place, however, was abandoned in the fifth century because of the formation of a lagoon. In the later sixth century, the port was moved to the new coastal stretch corresponding to the present Bovio Square, where it was settled for the whole Middle Ages (Giampaola et al. 2005: 47–91; Giampaola and Carsana 2010: 119–132).

According to Bartolommeo Capasso, the first scholar who located a port section in Municipio Square, the port of Naples was divided in two different basins separated by a strip of land. Capasso believed that the first and bigger basin, *Portus de illu Vulpulum*, was located in the present area formed by Castel Nuovo, Municipio Square, and Medina Street, while the second one, *Portus de illu Arcina*, smaller than the

other, was used by the Normans as a navy yard and located in the present area formed by Porto Street and Maio di Porto (Capasso 1881–1892: (377) 235–236). *Vulpulum* and *Arcina* were allegedly two sections of a whole port, not two portal basins. Whatever the real portal structure might be, Capasso has described the particular situation existing in 1018, when the document concerning the port was written. A document written in 839, instead, talks only about a «*portum Neapolim*», where Constantine, «*ypatus castri Kaietani*», would have sent 10 *modii* (=about 441 lb or 200 kg) of wheat to his sister Elizabeth and his nephew Theodore (Capasso 1881–1892: 263–264).

In 1018 the maritime city customs, managed by John Atalaricus, were connected to the Neapolitan port (Capasso 1881–1892: (377) 235–236). John Atalaricus is related to the famous suit brought by him against Pancratius, the Sts. Sergius and Bacchus' abbot. According to a privilege granted by the Neapolitan *Dux* John (allegedly in 999?), Pancratius refused to pay the import and export duties to Atalaricus. Sts. Sergius and Bacchus' privilege was recognized by the civic court once in 1018 and twice at the end of the eleventh century, when another Atalaricus led the city customs, almost as if customs were a family inheritance. This last information implies that even the city customs were one of the ex public offices subcontracted by *duces* to increase the public revenue. In my opinion, it is certain that the *Atalarici* were formally heirs of the Byzantine *kommerkiarios* or *parathalassites*, the customs officers in charge of collecting maritime duties. A *parathalassites* of Palermo is mentioned in a Greek inscription (1081) discovered in Sicily. According to Helene Ahrweiler, who has stressed the importance of this proof, the inscription shows that a Byzantine customs had been established in Palermo (Ahrweiler 1961: 245). But in the meantime, this proof is the reason that the presence of a maritime customs in Naples can be hypothesized for the Byzantine age. When the Neapolitan port was one of the main Byzantine ports in the Southern Italy, it was often chosen as a landing site by imperial dignitaries and ambassadors coming from Constantinople (Gundlach 1892: (17) 515, (58) 583–584, (82) 615–616).

Patrimonium Campaniae

The *Patrimonium Campaniae* was a part of the whole *Patrimonium sancti Petri*. Before the twelfth–thirteenth centuries, the *Patrimonium sancti Petri*, named by Byzantine sources as Saints Peter and Paul's *Patrimonium*, indicated the *latifundia* owned by the Roman Church: the expression, in short, meant patrimonial and not political control exercised by popes over those territories. It was a formal distinction, because from the eighth century, the Roman Church started to exercise a real political control over her *Patrimonium*.

The *Patrimonium sancti Petri* originated from the donations made by the Emperor Constantine to each church founded by him. From the sixth century, those properties were unified, and the new whole *Patrimonium* was moved under the pontifical control. During the age of Gregory the Great, *latifundia* of the *Patrimonium* were mainly located among Central and Southern Italy, Sicily, Sardinia, and Corsica. The same pope managed a new strongly centralized system to control the whole *patrimonium* which was divided into smaller local and regional *patrimonia*, composed of smaller properties called *massae* and *fundi*. Every single *patrimonium* was managed by a *rector*, an officer chosen by the pope and subject to him.

The first officer known for the *patrimonium Campaniae* is the *defensor* Constantine (558–560). The *rector* Theodimus is known in the eighth century, and he took part in John's siege of Cumae (716/717).

In my opinion, relevance of the *Patrimonium Campaniae* increased in the new Gregorian system. In September 591 the Neapolitan Bishop Demetrius had been already overthrown by Gregory (Greg. Mag. *Reg. Epist.* II, 3 = Recchia 1996–1999: 276–279), who, in Campania and elsewhere, often employed a sort of modern spoils system. Between 591 and 592, Gregory replaced the *rector* Anthemius (591; 594–603) with the Subdeacon Peter, a person identified by scholars with the famous homonym mentioned in the Gregorian *Dialogi* (Pietri and Pietri 2000: 1762–1771). Probably the troubles connected to

the political instability of that area, often vulnerable to Longobard assaults (581–591/592), and the weakness of the new episcopal vicarious, Paul of Nepi, chosen by Neapolitans as Demetrius' substitute, led Gregory to move his loyal and strong Peter (592–593) into Naples from Sicily. Peter could manage that situation better than both Anthemius and Paul. An improvement of the military situation, at least for Naples as *rector*'s headquarters, and a new stronger bishop, Fortunatus (593–600), led Gregory to recall Anthemius and replace Peter (Greg. Mag. *Reg. Epist.* IV, 31 = Recchia 1996–1999: 76–79).

Around the sixth–seventh centuries, the *Patrimonium Campaniae* located in the Dukedom of Naples was composed of the following: the «*possessio insula* cum *castro*», that is Nisida, the income of which was 80 *solidi*; the «*insulam Meseno* cum *possessiones ad eandem insulam pertinentes*», that is Cape Miseno, whose income was 810 *solidi*; and the «*possessio Macari*» (=the island of Megaride), in *castrum Lucullanum*, whose income was 150 *solidi* (Duchesne 1886: 170–187). Some other properties are attested in 719–731: the island of Capri, with the monastery of St. Vincentius and its jurisdiction; the monastery of St. Pancratius «*situm extra castrum Mesenate*»; the hamlets of Castromaiore and Ninfise (=*Nymfulas*?) located «*infra insulam Capris patrimonii Neapolitani*»; and «*lacum q. d. Iacaonia ex corpore patrimonii Campaniae Neapolim*». These last mentioned *latifundia* are known through the pontifical letters which document the rent paid to the Neapolitan *Dux* Theodorus (719–729) and a certain *religiosa diaconissa* Matrona (Kehr 1935: 429). The reason for this choice is unknown. It's highly probable that in the eighth century, the Papacy was unable to guarantee a profitable management of those properties and their rent was considered the most convenient economic solution.

Naples: Cathedrals and Episcopal Area

During the High Middle Ages, the episcopal area of Naples was a large architectural complex composed of a group of different buildings, often connected to each other. The main buildings of this area were the two cathedrals, Santa Restituta and Stephania, and this is why Naples has often been described by scholars in the improperly named «double cathedral» model. This complex was almost completely demolished between 1294 and 1314, when the new cathedral of Madonna Assunta was built by the Angioinian kings. In any case, some recent archaeological studies, centered on a reinterpretation of excavations carried out at the beginning of twentieth century, have shown how the episcopal area was allegedly organized during the High Middle Ages.

The episcopal complex was built between the fourth and fifth centuries in a residential area inhabited from the Greek age. The new use of the area caused its depopulation, so many old buildings were redeployed as religious buildings. According to the legend, the first cathedral of Santa Restituta was built under the reign of Constantine, at the beginning of the fourth century. But this version cannot be considered. Archaeologists have proved that Santa Restituta was built not before the fifth century. The same scholars have also discovered that in front of the church or at its side, there was a magnificent and large courtyard which allowed the different buildings of the area to be connected to each other. This courtyard can be identified with the courtyard discovered in the excavations of the episcopal *insula*'s Northern side, which had been wrongly identified before as the atrium of Stephania, San Lorenzo *ad fontes*, or *consignatorium alvatorum* built by the Neapolitan Bishop John III (615–636) (Ebanista 2016: 125–172).

Only a century later «*copulatam* cum *Episcopio*» (Waitz 1878: 409), the second Neapolitan cathedral, the Stephania, was built. It was so called because of its founder, the Bishop Stephen I (. . .ca. 495–499–500–502–510). Restored twice by John II *Mediocris* (533–553) and Stephen II, in both cases because of a fire which burned its apse, the church preserved a magnificent mosaic commissioned by John II (Waitz 1878: 410, 426).

John II also sponsored the building of San Lorenzo, known as San Lorenzo Maggiore, nowadays located in St. Gaetano Square, in Naples.

His successor, Vincentius (. . .558–559. . .), had restored and enlarged the paleochristian church of San Giovanni (Picone 2008: 40–41): this church, known as San Giovanni Maggiore, is the place where in the eighteenth century, a famous marble calendar made in the ninth century was discovered. San Giovanni Maggiore was restored once in the Angioinian age and twice in the nineteenth century. According to a Neapolitan source, the same Vincentius built the «*baptisterium fontis minoris intus episcopio et accubitum* (=triclinium or cenaculum) *iuxta positum grandi opere depictum*» (Waitz 1878: 412). This *accubitum* cannot be identified with the apse discovered in the excavations of the episcopal *insula*'s courtyard, on the Eastern side of the current Santa Restituta chapel, because the apse and its decoration were allegedly built around 475–525 (Ebanista and Cuccaro 2010: 521–530). Vincentius' operation followed the same as that led by Bishop Soter (. . .465. . .), who divided «*fontes maiores*» located in the episcopal area (Waitz 1878: 414). In the opinion of many scholars, this implied that Soter had allegedly restored the baptistery build by his predecessor, Severus (. . .387/393–397/398. . .), a baptistery which has been traditionally identified with the magnificent San Giovanni in Fonte, but actually this hypothesis seems to be weak and unfounded (Rotili 1978: 26–27; Ebanista 2016: 146–148).

In the episcopal area, Stephen II sponsored the building of the church of San Pietro (Waitz 1878: 425–426). Later Bishop Paul III (801–821) had built at the episcopal entrance a great *horreum* (=granary) with a *cubiculum* (=oratory) (Waitz 1878: 427). On the episcopal staircase, a *xenodochium*, a pilgrims' shelter, was built by Athanasius I (Waitz 1878: 434). In any case, the *horreum* and the *xenodochium* increased the Neapolitan welfare system composed of diaconies, baths, and monastic hospitals. All of these institutions allowed Neapolitans to be fed and cared for from the Late Antiquity to the Early Middle Ages, when they were forced to depend on public *frumentatio* (=wheat distribution system) and healthcare (Cilento 1969a: 670; Bozzarello 2015: 47–61).

Athanasius I, however, was the author of a project thought to give to the episcopal area a new architectonical organization, in which two cathedrals were arranged with better connection. This operation was followed by a liturgical reorganization of the same cathedrals. Therefore, he ordered the establishment of the ebdomadaries in Stephania, who had to celebrate a daily mass according to the Roman Church discipline, and a primordial cathedral chapter in Santa Restituta (*Vita s. Athanasii* IV, 35–40 = Vuolo 2001: 127–128).

Naples, Iconoclasm in (731/732–800)

Luca Bozzarello
Department of Humanities, University of Calabria, Arcavacata di Rende, Cosenza, Italy

State of Knowledge and Current Debates

Between 1970 and 1989 some among the historians interested in the Neapolitan Dukedom's events preferred to pay specific attention on the eighth century and, in particular, to the Iconoclastic period. This debate was animated mainly by P. Bertolini (1970: 349–440, 1974: 101–127) and P. Schreiner (1979: 113–128, 1988: 366–368). According to the traditional view (Gay 1980: 18; Schipa 1923: 33; Cilento 1969: 647–654), which has its roots in the seventeenth century (Chioccarello 1643: 70–71), Bertolini tried to confirm the adhesion of Naples to Iconoclasm through new proofs and inquiries. Schreiner instead worked to deny Neapolitan doctrinal Iconoclasm through a reconsideration of the same proofs used by Bertolini. In 1989, F. Luzzati Laganà participated in the debate supporting the thesis of Napolitan Iconoclasm. Her paper (Luzzati Laganà 1989: 99–115), however, conveyed too many influences coming from Bertolini's paper, especially in the exegesis of sources and revealed its own weakness in several passages. In 2005, the debate was resumed by

J.-M. Martin, who, as well as Schreiner, denied any kind of doctrinal Iconoclasm in Naples (Martin 2005: 62–64).

Status quaestionis concerning issues of Neapolitan Iconoclasm has been recently summarized by A. Acconcio Longo, who, following Luzzati Laganà, has considered a short and almost irrelevant application of doctrinal Iconoclasm in Naples highly probable (Acconcia Longo 2012: 221–238). The historical debate is mainly related to the interpretation of some of *Gesta episcoporum Neapolitanorum*'s passages (Waitz 1878: 422–425) – passages that have been read by Acconcia Longo with appropriate scientific acuity. So, if a new reconsideration of the so-called Neapolitan Iconoclasm is possible nowadays, it is above all for her contribution. No elements or relevant proofs can be taken from hagiography, numismatics, and sphragistics (Bozzarello 2017: 127–128). Scholars have shown that the mention of Naples "*et le régions située jusqu'au fleuve de Rome*" (Auzépy 1997: 219) as shelter for Iconodules could describe the real situation lived in those territories, not at the time of St. Stephen the Younger's martyrdom (765) but more than 50 years later, when the hagiography was composed (807/809) (Auzépy 1997: 5–9; Acconcia Longo 2012: 224; Martin 2005: 62–64). St. Januarius' representation on the 20 *nummi*'s *recto* (Sambon 1919: 71–73) is allegedly related to the consolidation of his veneration among the Neapolitans and the ducal family as well (Schreiner 1988: 366–368; Bozzarello 2017: 128–129). In any case, the replacement of the previous representation of Emperor Leo III (717–741) with the one of St. Januarius has to be interpreted as a free choice made by the Neapolitan Mint according to the freedom concerning figurative issues granted by Byzantium to the peripheral Mints (Arslan 2005: 1059–1096). Also, in coeval Neapolitan seals religious characters are often represented. But in both cases, coins and seals repeated artistic codified models very common across the Byzantine world (Bascapé 1969: 178–180).

Concerning *Gesta*, instead, the sprain of a sheet which once worked as a union-sheet between its first part (eighth/ninth century) and its second part (tenth century) – joined together in *Vat. Lat.* 5007 during the thirteenth century – has been often considered a censorship done by Iconodules after their definitive victory (Bertolini 1974: 113–127; Acconcia Longo 2012: 104); but a sheet-spread has been instead denied by Schreiner (1979: 124–125; Schreiner 1988: 367). It is a break which occurs in Bishop Calvus' biography (750–762), significantly in its part concerning some heroic ventures managed by *Basileus* Constantine V (741–775). Indeed, similar and coeval tales have survived in Armenia with no censorship (Gero 1973: 135–136) because these kinds of tales have no relationship with Iconoclasm: they are simply related to imperial propaganda involved in describing Constantine V as a protector of his subjects (Acconcia Longo 2012: 221–237).

Definition

Iconoclasm (from εἰκονοκλάστης, "image-destroyer") was a religious movement of the eighth and ninth century that denied the holiness of icons and rejected icon veneration. Clerical opposition to the artistic depiction of sacred images had its roots at the beginning of Late Antiquity, but the birth of icon veneration across Western and Eastern Christians can be set around the seventh century. Iconoclasm became a movement when Emperor Leo III began to support it publicly in 726 and to ratify on the 7 January 730, through an edict commanding the destruction of the icons of the saints. This destruction was revealed by removing the famous icon of Christ placed on Chalke Gate, despite the opposition of the Patriarch of Constaninople, Germanos I. In any case, the persecution under Leo III appears to have been limited to instances of destroying church decorations, portable icons, and altar furnishings or, according to the latest interpretations, limited to instances of moving icons into hidden spaces of churches, and removing icons and relics placed near the altar. Leo's operation, however, was distant from the radicalism and violence of his son Constantine V, who, after a temporary restoration of Iconodulism imposed by usurper

Artabasdos, summoned a council in Hieria (754) where the 338 bishops there assembled ratified once again imperial Iconoclasm. Iconoclasm waned after Constantine's death, and *Basilissa* Irene (797–802), ruling for her 10-year-old son Constantine VI, together with patriarch Tarasios secured an official condemnation of Iconoclasm at the Council of Nicaea II (787). However, old and new disagreements across followers of the Iconodule party led to a new rebirth of Iconoclasm, which had its last phase in 815–843 (Gero 1973: 94–122, 129; Kazhdan et al. 1991: 975–977; Gallina 1997: 152–179; Noble 2009: 10–45; Brubaker and Haldon 2011: 32–66, 151–155)

Historical Development

Iconoclasm was allegedly extended to the Western Byzantine provinces, including Southern Italy, in 731/732. The dioceses of Illirycum, Crete, Calabria, Sicily, Sardinia, and Naples were transferred from the authority of Rome to the authority of the Patriarchate of Constantinople. This measure, which was ecclesiastic in nature, incidentally drew a new map of Byzantine Italy, designating Sicily and Calabria as preferred areas of the Byzantine Empire, following the way already thought by Constance II (641–668). The enlargement of the Constantinopolitan Patriarchate was lawfully arranged according to counciliar canons in which ecclesiastical geography was tightly tied to civil geography. Actually, it was the revenge of the Empire against the Roman Church, that in 724/725 had refused to devolve the Italian province's duties to Byzantium and later condemned Iconoclasm in the Roman synod of 731. All these operations favored the birth of the separatist movement of the Exarchate and *Venetiae*, which, searching for freedom from Byzantium (726/727), was then defeated in 727 by Exarch Eutichius. In any case, in 731/732 Byzantium was trying to create in Southern Italy a national Church united by the common denominator of Greek culture (De Boor 1883: 404–413 = Mango and Scott 1997: 558–573; Paol. Diac. *Hist. Lang.*, VI, 49 = Zanella and Luisella 2014: 532–533; Anastos 1957: 14–31; Guillou 1969: 209–227, 1977: 105–106, 1988: 30–31; Burgarella 1988: 320–323, 1989: 438–446; Von Falkenhausen 1982: 36–40).

Leo's measure was actually a seizure of pontifical *latifundia*. Abrogating the Roman Church's fiscal exemption given by Emperors Constantine IV (668–685) and Justinian II (685–695; 702–711) (Burgarella 1988: 320–323, 1989: 438–446), Leo III allowed the Empire to seize the whole fiscal revenue coming from *Patrimonium sancti Petri* located in Theme of Sicily and Dukedom of Calabria, which, according to an estimate done by Guillou (1977: 105–106, 1988: 30–31), consisted in ca. 5,25 talents of gold (=373.332 *solidi* or *nomìsmata*) (De Boor 1883: 410 = Mango and Scott 1997: 568). It is highly probable that in the Byzantine Campania pontifical properties were simultaneously seized, even if this seizure is attested to by proofs not before 764–766 (Gundlach 1892: (37) 547–550; Kehr 1935: 420).

According to *Gesta* (Waitz 1878: 422), almost simultaneously at his designation (717) the new bishop of Naples, Sergius, was elevated to archbishop by the Patriarch of Constaninople, but he quickly refused the new rank because of the Pope's opposition. Therefore, Sergius was absolved, but not before having publicly renewed his obedience to Rome. These events, indeed, should be referred to the period after 731/732 and connected to Leo's reform. This interpretation could be demonstrated through proof handed down by St. Willibald's *Itinenarium* in which Naples is described as an archbishopric, so with the rank that Naples probably had when Willibald was living in Monte Cassino between 729 and 739 (*Vita s. Willibaldi* 31 = Tobler and Moliner 1879: 273; Burgarella 1988: 310–312). While the renting of some Neapolitan pontifical *latifundia* granted by Pope Gregory II (719–731) to *Dux* Theodorus (719–729) and to a certain *religiosa diaconissa* Matrona (Kehr 1935: 429) could be read as the proof of political and administrative arrangements still unmodified before 731/732. The reason of this rent is allegedly economic. In the eighth century, the Papacy was unable to guarantee a profitable management of those properties,

and their rent could have been considered the most convenient economic solution.

Once it was raised to the rank of archiepiscopal so autocephalous see, Naples became independent from its lawful patriarch, the Pope. Thus, Naples became a second Ravenna, a city elevated to autocephalous see by Constance II in 666 (Guillou 1969: 209–227). Implicit was the Byzantine drawing to give to Naples a central role in the new Italian ecclesiastical geography, transforming bishoprics located across the peninsular Mezzogiorno into territories subjected to the new metropolitan see (Von Falkenhausen 1982: 36–40). A measure which would have facilitated imperial seizure of the whole *Patrimonium sancti Petri* located in Southern Italy.

Iconoclasm in Naples was a fiscal-political issue and not a doctrinal issue (Schreiner 1988: 366–368; Martin 2005: 62–64). A document dated 763 can be considered the proof that the Neapolitan diocese was still under the authority of the Roman Patriarchate (Capasso 1881: (2) 262–263). So the later exile of the Neapolitan Bishop Paul II (763–767), often wrongly interpreted as the proof of an Iconoclastic Naples, appears to have been the answer given to Rome by the civic establisment that was trying to assume and reaffirm autocephalous see's lawful rights. According to *Gesta* (Waitz 1878: 424–425), Paul, who had been chosen by Pope Paul I, his friend, was consacrated in Rome 9 months after his appointment. But when he came back to Naples, the Neapolitans, who were followers of the Iconoclasm, refused him and he was exiled from the city. His exile ended 2 years later, around 764/765, when Neapolitan *primates* allowed him to move again into the city. According to G. Cassandro (1969: 41) a letter dated 764–766 is probably related to this event. Through this letter Pope Paul I thanked Pepin, King of the Franks, for the threats against authorities of Gaeta and Naples carried out to restore the old procedure which allowed elected bishops to be consacrated in Rome by the pope (Gundlach 1892: (37) 547–550; Kehr 1935: 420). So Neapolitan *primates*, fearing a conceivable Carolingian invasion, could have thought to withdraw their veto.

In the eighth century, the Neapolitan authority appears to be involved in controlling the elections of bishops. Sergius was imposed by *Dux* John (711–717). According to *Gesta* his election was the accomplishment of an *ex voto* for the Neapolitan victory at Cumae over the Longobards (716/717). Perhaps also Bishops Cosmas (748–750) and Calvus were imposed by *duces* and their party. On the contrary, Paul should have been the candidate of the clergy. The election of bishops, indeed, was still formally delegated to the city assembly formed by clergy, aristocracy, and *populus*, which chose its candidate through public acclaim. Only a rebirth of the party close to the Neapolitan establisment allowed *Dux* Stephen II to be elected bishop at Paul's death. This is the meaning of John Diaconus' words, author of the second part of the *Gesta*, who has described the election of Stephen as related to the death of all Neapolitan clerics because of the plague (Waitz 1878: 426; Bozzarello 2015: 57). Even if the ecclesiastical canons forbade laic men from participating in episcopal elections, the appointment of Stephen was confirmed and ratified by the Pope as it had earlier been done in Ravenna by consecrating Sergius (Bertolini 1970: 402). Enjoying the favor of Neapolitans, Stephen could manage to take the whole control of the Dukedom in order to avoid conceivable clashes between the highest authorities of the Dukedom and their loyal parties. Therefore, troubles related to the election and assignment of the Neapolitan bishops across the eighth century appear to have been political conflicts between hostile parties, which are often attested to in the Mediterranean cities and in Naples as well, especially during episcopal elections (Patlagean 1986: 93–126; Bozzarello 2017: 68–80, 143–151).

Stephen was actually the leader of the Neapolitan policy in the second half of the eighth century. (767/768–800). He managed a strong policy of Latinization of the Neapolitan Church and its institutions, indicating the way then followed by Bishops John IV (842–849) and St. Athanasius I (849–872) (Bozzarello 2017: 152–157). According to Rome, he was a strong opposer of doctrinal Iconoclasm, as some of his choices in art and architecture clearly show. A good example of his

policy is represented by the building of St. Peter's church in the episcopal area (Waitz 1878: 426; Luzzati Laganà 1989: 110–111; Lucherini 2009: 51–73). Here, at its entrance, he ordered the painting of the first six Ecumenical Councils as a protest against the coeval removal of the same images at Milion of Constantinople ordered by Constantine V (Waitz 1878: 426; Luzzati Laganà 1989: 110–111). In the meantime, he was also a loyal imperial officer by refusing to delete the seizure of pontifical properties located in Dukedom of Naples. This is shown by events occurring in 779–780 and related to the invasion of Terracina, managed by "*nefandissimi Neapoletani cum perversis Grecis*." Terracina, *castrum* placed under "*dicione beati Petri*," had been occupied by Neapolitans together with Byzantines following Arechis II's advice. According to sources, Pope Adrianus I would have surrendered Terracina to enemies in return for Neapolitan *Patrimonium Campaniae*. But this pact failed once again because of Arechis' intrigues, and the Byzantine seizure of "*patrimonium* (…) *beati Petri apostoli, quod ibidem in Neapoli ponitur*" continued (Gundlach 1892: (61) 588–589, (64) 591–592; Kehr 1935: 420, 430).

It is highly probable, moreover, that this seizure was confirmed after the Council of Nicaea II when Iconodulism was re-established as a cult only. This had been possible thanks to the division between fiscal and doctrinal issues, a measure which was approved in Sicily and Calabria, lands of strong hellenization. While, at the same time, it was disapproved by Pope Adrianus I, who, before the formal Council's openining, had asked for the restitution of *Patrimonium sancti Petri* located in Mezzogiorno still seized by the Byzantines (Burgarella 1988: 331–331, 1989: 446).

Narrative and Storytelling for Archaeological Education

Adrian Praetzellis
Sonoma State University, Rohnert Park, CA, USA

N

Introduction

The aphorism "Archaeology is… the driest dust that blows" is credited to Mortimer Wheeler, one of the great popularizers of archaeology. Storytelling is one tool to prevent this fate and to make the past accessible to the present. Although it involves creating narratives using archaeological information, storytelling is not merely inventing fanciful stories to rescue children from classroom boredom. As this section is located in the Public Education category of this publication, the reader might assume that storytelling is a one-way process, something professionals (producers) do for the edification of the public (consumers). But this is only part of the story. As something that insiders do for the uninitiated, this is an epistemologically safe approach that draws a hard line between an intellectual pursuit that deals in hard data and the emotional response of encountering the lived

experiences of people in the past. To suggest the latter opens archaeologists up to personal vulnerability. If archaeological storytelling were only a pedagogical technique, it would be of little interest to non-teachers. On the contrary, storytelling has both didactic and reflexive benefits. It has value for both its creators and their audience. But what is storytelling? Who is the public and what are they being educated about?

Definition

A story is a piece of prose or poetry that has narrative structure which, according to archaeologist Mark Pluciennik (1999), involves characters, events, and plotlines. For the present purpose, archaeological storytelling means the creation of prose, poetry, performance, song, or other mode by an archaeologist that incorporates archaeological data, has narrative structure, and that transcends standard archaeological presentation. I exclude most mass-market novels from this genre, as they are understood to be inventions regardless of how deeply they may draw from the archaeological record. I distinguish between products created explicitly for public outreach and those created both by and for archaeologists themselves. There is obvious overlap here, but at some point definitions are odious.

Why "storytelling"? I have used the term to de-intellectualize and separate the fledgling practice from the near impenetrable argot of literary theory (Praetzellis 1998). "Telling stories" has an intentional naivety that contrasts with the self-conscious and theoretically loaded "constructing narratives." To some degree and for some practitioners, storytelling is an attempt to regain part of archaeology's lost innocence. It encourages the reader to empathize with the characters, to enter their world and recognize their humanity. Narrative evokes an emotional rather than an intellectual response: coming across the skull of "poor Yorick," Hamlet reflected on mortality, not physiology. "Narrative 'truth'," wrote Bruner, "is judged by its verisimilitude rather than its verifiability" (1991: 13).

Key Issues/Current Debates

The rise of the narrative genre in the fields of history and archaeology is an outgrowth of intellectual movements of the 1960s and 1970s that lead away from the scientific, generalizing explanation of past events and processes to a more descriptive mode (Stone 1979). Hayden White's (1973) essay expressed what many historians had been thinking for years: that primary texts themselves are historical interpretations. At the same time, cultural anthropologist Clifford Geertz claimed that ethnographic descriptions are "not privileged, just particular: another country heard from" (1973: 23). Postmodern skepticism with the metanarratives of the past gave a new respectability to the study of the small scale and local.

While historians delved into micro-history, archaeologists too began to people the anonymous past. The household was well suited to tease out gender relations that were often more visible at this scale of analysis (e.g., Spector 1993). Phenomenology became a useful method at larger scales: Mark Edmonds (1999), for example, reconstructed how ancient peoples may have experienced their cultural landscape. Edmonds' narratives and the work of Chris Tilley (1997) leave one wondering how it is possible to appreciate the functioning of a ritual structure without considering the emotional responses of the people who used it.

One of the outcomes of archaeology's loss of innocence is that each generation must puzzle over how it can remain authoritative while being honest about its epistemology. Narrative and phenomenological approach are subject to frequent critiques from within archaeology. These concern both the intellectual validity of these approaches (e.g., Fleming 2006) and the possibility that archaeology as a field may lose its credibility with the public – and consequently its funding – if practitioners stray from conventional scholarship. Blur the distinction between what we know with some level of certainty and what we merely speculate, and the ice becomes thin indeed (Kristiansen 2011).

While it lived in the rarified atmosphere of the academy, archaeology shared the protected status

of many another esoteric specialty. But the rise of legally mandated and public-funded archaeology since the 1980s injected another consideration: the necessity to justify archaeology's cost by an equivalent public benefit. "Telling the stories" of places listed on the USA's National Register of Historic Places involves a range of modes including drama (Thomson and Harper 2000), while fictional accounts based on archaeological and archival sources have been used for decades to present the results of legally mandated archaeology to the general public (e.g., Praetzellis and Praetzellis 1984; Kane and Keeton 1994).

For the practitioner writing about his or her site, storytelling gives the freedom that only comes with an explicitly personalized narrative. The necessity to maintain an objective stance is gone. Invented dialogs invite intellectual thought experiments about potential meanings. Seemingly mundane objects can be explored and recontextualized regardless of their apparent scientific significance. And the standard site report's seamless teleology can be mangled by pursuing one or other of the odd quirks that influenced the investigation. One outcome is esthetic, for the creator derives fulfillment from the creative process by which he or she constructs a reality in which "their" people interact with the objects and documents that have come to be familiar with the investigator. Simultaneously, it is an exercise in reflexivity, a reminder to archaeologists that we ourselves assign meaning and pattern from a range of possibilities.

Examples

Archaeological narrative has several audiences (including the creators themselves) and has many forms. In this section, I present examples of the form organized by structure or mode, since this is how the audience experiences it. The modes are stories, pedagogical dialogs, performances, and novels.

Stories often take the form of archaeologically informed descriptions of mundane events whereby the archaeologist presents site formation processes, for example, the stories that form the introduction to Deetz's (1996) book *In Small Things Forgotten* that include the purchase of some pots that might be later found by an archaeologist. Stories may also attribute theoretically informed motives to the characters as in Spector's wonderfully empathetic *What this Awl Means* (1993). In recent decades, archaeologists have become less timid about straying from the straight road of science and into the potentially treacherous paths of phenomenology. Tilley (1997) is one of the best exponents of an archaeology that inserts emotional response into the understanding of Neolithic landscapes to figure out how people experienced the ritual structures they created. Interpreting publically funded archaeological investigations, the audience for stories is as wide as can be, including the general public, students, and archaeologists.

Dialogs pit characters' opposing views against each other in more or less realistic conversations often about the nature of archaeological discourse itself. In the premiere example, Flannery's (1982) moral tale *The Golden Marshalltown*, the Old Timer matches wits with an ambitious, amoral upstart over what it means to be a real archaeologist. Dialogs have been a popular pedagogical technique since Socrates, as the writer sets up questions and answers to echo the natural give-and-take of natural argumentation. In Johnson's popular textbook *Archaeological Theory* (2010), the useful but annoying foil Roger Beefy (who loves archaeology but can't see the point of all that theory stuff) interjects many of the empiricist, common sense remarks that are so familiar to undergraduate teachers. My own textbook *Death by Theory* (Praetzellis 2011) attempts something similar in the guise of a cartoon-illustrated murder mystery novel. The audience for dialogs – whose authors intentionally avoid the jargon and convoluted construction that baffles the uninitiated – tends to be university students and professional archaeologists.

Performances and multimedia presentations include pieces created primarily to be experienced in real time by an audience rather than to be read from a book. The emphasis is often on the emotional impact created by theatricality as a reflexive and possibly transformational experience for

fellow archaeologists at a professional venue (e.g., Praetzellis and Praetzellis 1998). Bapty's (1990) play "The Agony and the Ecstasy" is an internal dialog about the creation of the past through interpretation through the Inward voice, the Outward voice, and the Past. That the audience is other archaeologists is made clear by the fact that the action takes place at 3:10 p.m. on 19 December 1990 at a particular academic conference: the Theoretical Archaeology Group meeting in Lampeter, Wales. The use of Web-based hypertext documents in archaeology is exemplified by Rosemary Joyce's Sister Stories project that began in 1994 (Lopiparo and Joyce 2003). Seeking an alternative way to interpret archaeological insights, Joyce hyperlinked portions of the sixteenth-century Florentine Codex (a sixteenth-century ethnography of the Nahuatl-speaking people of the Aztec empire) onto a map at locations that would have been familiar to these people. Finally, there are Tringham's movies that reflect, among other things, on archaeologists' complex emotional relationships with their sites. "Back in My Hometown" (Tringham 2010), for example, was created for and aired at the 2010 Society for American Archaeology conference, while the multimedia RAVE (Real Audiences and Virtual Excavations) was Tringham's keynote address at the 2003 Society for California Archaeology conference.

Archaeo-historical novels consist of prose storytelling on a grand scale. While individual stories tend to interpret particular short-lived events, these novels often have complex storylines that extend over long periods. What separates work in this category from conventional historical fiction is their level of documentation – archaeological, documentary, and ethnographic. It is no accident that this mode is often selected by senior archaeologists who use the medium to reflect on archaeological interpretation and their own role in the process. These people have decades of experience to offer and, as recognized scholars, are less susceptible to the kind of criticism for venturing into the narrative mode that might derail a less established career. Layton's novels (1999, 2002) imagine the origins and eventual disposition of the cargo of a vessel that wrecked off the California coast through the eyes of Native Americans, seamen, and the sport divers and archaeologists who eventually brought the collection to light. In contrast to Layton's books, which are extensively footnoted to the archaeological and sources upon which the author relied, are Nelson's mystical novels of Neolithic Korea (1999, 2004). Footnotes would only disturb the flow of these lyrical works through which the author convincingly peoples the ancient past to explore gender, shamanism, and ethnic identity. The audience for archaeo-historical novels ranges from the general public to university students and professional archaeologists.

Nasca and Pampa Jumana Lines and Geoglyphs

Persis B. Clarkson
Department of Anthropology, University of Winnipeg, Winnipeg, MB, Canada

State of Knowledge and Current Debates

Thousands of giant ground drawings scribed by ancient inhabitants onto the Pampa Jumana of southern Perú in the Río Grande de Nazca ("Nasca" refers to the archaeological culture; "Nazca" refers to geographic locations) drainage are known as the "Nasca geoglyphs" or "Nasca lines." Artifacts associated with the geoglyphs suggest that they were known and used as early as the Early Horizon through Inca domination (Table 1).

Although the region lies on the northern extent of the arid Atacama Desert, adjacent river valleys are generally reliable sources of water and excellent soils for agriculture and habitation. The Pampa Jumana, measuring approximately 3 × 10 km, contains the densest concentration of geometric and biomorphic figures. Geoglyphs, predominantly geometric beyond this bounded region, are found north in the Palpa Valley and south of Nazca along the foothills of the Andes mountains (MAP). The style and content of many of the geoglyphs echo other forms of artistic expression of pre-Nasca and Nasca cultures, while other geoglyphs appear to lie outside the known artistic corpus.

Nasca and Pampa Jumana Lines and Geoglyphs, Table 1 South Coast of Perú cultural chronology

Formative Period	1800-800 BCE
Early Horizon (Ocucaje)	800-200 BCE
Early Intermediate period (Nasca)	200 BCE – 650CE
Middle Horizon (Huari influence)	650-1000 CE
Late Intermediate Period (Ica)	1000-1450 CE
Late Horizon (Inca)	1450-1532 CE

N

The geoglyphs were noted in 1926 by the archaeologists Kroeber, Tello, and Mejia while they were undertaking archaeological survey in southern Perú (Mejia Xesspe 1940). The sixteenth-century Spanish chronicler Pedro Cieza de León may have referred to the geoglyphs in 1553, and in 1586 the provincial magistrate Luis de Monzón referred to "caminos" – roads – in southern Perú that were likely the long linear geoglyphs abundant throughout the region (Clarkson 1985).

Systematic studies of the Nasca geoglyphs began in the 1940s and have expanded to explore their role in the worldview and lifeways of the inhabitants of the region, including astronomy, calendars, religion, and agriculture. Scholarly research in the Nazca region has been broad based, encompassing archaeology, history, ethnography, art history, hydrology, geology, and geography (Kosok 1965; Reiche 1980; Reinhard 1985; Hadingham 1987; Morrison 1987; Aveni 1990, 2000; Aveni and Silverman 1991; Rickenbach 1999; Silverman and Proulx 2002). More recent research has included the use of remote sensing technologies to identify additional archaeological sites related to geoglyphs, particularly in the adjacent region of Palpa (Isla and Reindel 2005; Sauerbier et al. 2006; Lambers and Sauerbier 2009; Reindel and Wagner 2009). Additionally, much literature on Nasca geoglyphs falls within the realm of unsystematic research, and Nasca culture and geoglyphs are perhaps better known for popularized fantastic claims that have little or no context within Andean culture history. Such claims deny the ingenuity, creativity, and intelligence of a rich cultural adaptation that thrived for hundreds of years in one of the driest deserts in the world.

Nasca geoglyphs are intentional human-created renderings of biomorphic, geometric, and abstract forms and are situated on stable surfaces of the desert adjacent to the river valleys of the region. There is evidence of use and reuse of the geoglyphs, beginning with the Early Horizon.

The manufacture of geoglyphs was easily accomplished, requiring neither great strength nor large numbers of people; the execution of the geoglyphs did require forethought, planning, and skill. The desert surface is a natural palette, comprised of light-colored alluvial outwash from the Andean foothills, overlain by stones with dark-colored desert varnish. A "subtractive" geoglyph is made by removing or sweeping aside stones to reveal the lighter-colored substrate in sharp contrast. An "additive" technique provides visual definition to a geoglyph by contrast and shadows cast by low continuous mounds of stones swept aside to outline the desired form. Both manufacturing techniques are stable enough to withstand substantial winds, rain, and earthquakes. The need invoked in the popular literature for aerial viewpoints to see the geoglyphs disregards the parameters of Nasca geoglyphs as non-static images and presupposes a Western tradition of viewing "art" on a vertical surface. The linear geoglyphs are easily visible from the ground from a fixed point on the geoglyph. Conversely, the biomorphic figures, measuring up to 125 m, cannot be fully seen from a static location; there are no natural elevated locations from which the biomorphic figures can be seen, and there is no evidence of constructions. The biomorphic figures were rendered by a single line the width of a walking path that delineates the figure; "seeing" a figure requires experiencing it by walking through the shape.

The motifs of Nasca geoglyphs include naturalistic and abstract (biomorphic) and geometric forms. Flora and fauna associated with motifs on ceramics, textiles, gourds, and other contemporaneous media provide information on naturalistic and abstract imagery. Geometric lines, trapezoids, and spirals are widespread throughout the Nazca region. Straight lines associated with "line centers" emanate from natural projections of the Andean foothills onto the pampas; these lines range up to several kilometers long. The lines extend unerringly straight, regardless of the terrain, suggesting a necessity of form that ignores convenience and suggests ritual walking. The geometric forms are not clearly identifiable in other forms of Nasca material culture, although Andean concepts of radiality associated with kinship, society, numerics, toponomy, and calendrics can be correlated with radiating forms of line centers.

The locations selected to create geoglyphs were deliberately and carefully chosen to avoid areas affected by water. The annual rise in the rivers running through the region, resulting from seasonal precipitation in the Andes, is confined to the rivers, and water flow through the pampa quebradas is minimal and predictable. An exception is found in long straight lines which can run for several kilometers, many of which cross seasonal watercourses. When a line cannot be seen on the opposite side of a watercourse, a cairn is usually present to guide the direction. Geoglyphs are also situated on the flanks of low alluvial hills; the visibility of these figures is assured by their elevation (Clarkson 1985).

The purposes and ages of the Nasca geoglyphs have remained at the core of investigations, and applications of new hypotheses and technologies continue to spur debate, reexamination, and reconsideration.

Water has been the basis of several studies over the decades. The water table is alternately very deep on the pampa – i.e., inaccessible – and accessible in the river valleys via natural springs and *pukios* (system of wells and subterranean aqueducts). Seasonal rainfall in the Andes results in an increase in water in the pukios and ability to maintain permanent habitation and agriculture (ONERN 1971). The necessity of assuring reliable water generates cultural responses that are elaborated through ethnographic comparisons that are based on documented factors of Andean cultures (Reinhard 1985; Urton 1990). The pukios are an ingenious water control system built where there was accessible water; the ancient builders not only mentally and physically connected springs with a fluctuating water table where it was relatively close to the surface at the valley bottoms, they avoided unnecessary evaporation of precious water (Clarkson and Dorn 1995; Schreiber and Lancho 1995, 2003).

The twentieth-century rediscovery of the Nasca geoglyphs prompted speculation about their antiquity, particularly because they lack obvious cultural contexts to date them. In spite of controversies about viable dating methods and results (Whitley 2009), independently derived ages (Silverman and Browne 1991; Dorn et al. 2001; Greilich et al. 2004) indicate that the majority of the geoglyphs were made during Nasca culture.

Maximum age estimates can be ascertained by dateable artifacts encountered on geoglyphs. The first systematic age estimates for the geoglyphs of the Pampa Jumana were derived by these means (Hawkins 1974; Clarkson 1990), associating biomorphic geoglyphs within the Nasca culture and geometric geoglyphs with the later Ica culture. The area has been repeatedly traversed since the arrival of Europeans in the sixteenth century, and such age determinations can be confused by more recent visitors redepositing or removing archaeological materials. The time lag between the creation of a geoglyph and deposition of artifacts, either through accident or by design, is indeterminate through this method. Similarly, a ^{14}C age of 525 ± 80 CE obtained by Strong in 1957 from a wooden post in a geoglyph provides no direct evidence of the association of the wood with the geoglyph.

Intrusive features associated with geoglyphs may provide a relative chronological sequence. Aerial photographs can show overlapping geoglyphs, a distinction that is difficult to observe from the ground; the lapse of time between the geoglyph creations is also indeterminate.

Bioarchaeological research related to the Nasca geoglyphs has further added to information about the ages of the geoglyphs, plus the people who were associated with them through ritual and burial. These participants originate both locally and from distant locations in Perú (Conlee et al. 2009; Knudson et al. 2009).

A series of ^{14}C assessments were made on desert varnish on pukios and geoglyphs in the Nazca region in the late twentieth century; the results were and are considered experimental, irrespective of the confirmed fraudulent accusations that the widely tested methodology was rigged (Whitley 2009; Dorn and Krinsley 2011). Significant advances and refinements of the methods to date desert varnish have been developed by Tanzhou Liu (2003; Liu and Broecker 2000, 2007, 2008a, b). Oxidizable carbon ratio (OCR) dating provided viable ages for geomorphological features at Nasca, and this dating

technique can provide more statistically viable ages for geoglyphs (Dorn et al. 1992; Dorn 2004: 18). Optically stimulated luminescence (OSL) has also proved to be a viable means of dating geoglyphs (Rink and Bartoll 2005).

There is no doubt that the geoglyphs were reused: there is no evidence to indicate that the original purpose for which a geoglyph was made maintained an identical use or meaning for ensuing generations or cultures. Astronomy, ritualized travel, pilgrimage, and metaphorical and allegorical water conduits between the Andes mountains and the river valleys (Reinhard 1985; Aveni 1990; Silverman 1993; Vaughn and Van Gijseghem 2007) are well-substantiated hypotheses. Geoglyphs considered within the context of related symbols on ceramics, textiles, and architecture provide insightful information on the environment, subsistence, and belief systems.

Damage and destruction by humans remain the greatest threat to the Nasca geoglyphs, where even footprints persist for decades. The natural environment has remained stable since before human occupation of the region. Rainfall and inundation on the geoglyphs is virtually nonexistent, and the frequent winds are insufficient to dislodge the stones that comprise the geoglyphs. Conservation and protection of the Pampa Jumana is enshrined by Peruvian law, and Nasca geoglyphs were granted World Heritage status in 1994. In spite of rigorous protection, the Nasca geoglyphs and region have been plagued by an increase in land squatters looting, and vandalism (Lasaponara et al. 2012; Lasaponara and Masini 2016; Masini et al. 2016; Tapete et al. 2013). In 2014 Greenpeace activists left a protest message in the midst of the concentrated area of geoglyphs, causing an international uproar and a rapid apology from Greenpeace (Greenpeace 2014).

Nash, George

George Nash
Department of Archaeology and Anthropology, University of Bristol, Bristol, UK
Geosciences Centre, Coimbra University – (u. ID73-FCT), Coimbra, Portugal
Instituto Politécnico de Tomar, Gabinete de Relações Internacionais, Quinta do Contador – Estrada da Serra, Tomar, Portugal
Center of Geosciences of the University of Coimbra, Coimbra, Portugal
Earth and Memory Institute, Polytechnic Institute of Tomar, Tomar, Portugal

Basic Biographical Information

Dr. George Nash is currently an associate professor, a senior researcher at IPT Portugal, and a lecturer at the Museum of Prehistoric Art (Quaternary and Prehistory Geosciences Centre, Macao, Portugal). George has been a professional archaeologist for the past 30 years and has undertaken extensive fieldwork on prehistoric rock art and mobility art in Chile, Denmark, Israel, Indonesia, Malaysia, Norway, Spain, and Sweden (Fig. 1). Between 1994 and 1997, he directed excavations at the La Hougue Bie passage grave on Jersey, one of Europe's largest Neolithic monuments, and has directed excavations at the World Heritage Site and Grade I listed building of Westminster Hall, London.

Nash, George, Fig. 1 Dr. George Nash

Major Accomplishments

George Nash has written and edited many books on prehistoric art and prehistoric monumentality including *Status, Exchange and Mobility: Mesolithic Portable Art of Southern Scandinavia* (1998), *Signifying Place and Space: World Perspectives of Rock Art and Landscape* (2000), *European Landscapes of Rock-Art* (2002) (Fig. 2), *The Figured Landscapes of Rock-art: Looking at Pictures and Place, edited with Christopher Chippindale* (2004), *The Architecture of Death* (2006), *Art as Metaphor* edited with Aron Mazel and Clive Waddington (2007) (Fig. 3), *The Archaeology of People and Territoriality* (2009) and *The Levantine Question* (2012) and, *the most recent publication Archeologies of Rock Art: South American Perspectives* (2018).

Nash, George, Fig. 2 *European Landscapes of Rock-Art* (Edited by George Nash and Christopher Chippindale (Routledge))

Nash, George, Fig. 3 *Art as Metaphor: The Prehistoric Rock-art of Britain* (Edited by Aron Mazel, George Nash, and Clive Waddington (Archaeopress))

Dr. Nash has authored 120 peer-reviewed papers and has edited, co-edited, and written over 30 books. George is currently involved in four major rock-art recording and interpretation projects in the central Andean region of Chile, the Golan Heights and Negev desert of Israel, and the Val Camonica in Northern Italy, looking at Iron Age house carvings. In Wales, he is co-director of the Welsh Rock Art Organisation (WRAO) and is about to coordinate and direct a rock-art landscape project in Staffordshire, Central England. He has also written and presented programs on European rock art and contemporary graffiti for the BBC and has presented programs in Europe and North America. George is also currently involved in two projects: a pigment analysis on painted imagery in Iberian megaliths and establishing a prehistoric rock-art inventory for Wales.

Since 2009 George Nash has directed a number of major field projects including an excavation of a Neolithic gallery grave in Delancey Park, north of St. Peter Port, Guernsey, part of a 3-year project, and a Neolithic portal dolmen in South West Wales. In 2010, George made the discovery in a South Wales cave of Northwestern Europe's oldest rock art which was dated using uranium-series disequilibrium dating methods to c. 14,505 BP.

In 2011 and as part of his ongoing publishing commitments, George has co-edited and published two seminal works, *European Landscapes of Rock-Art* (2002), with Christopher Chippindale (Fig. 2) and was also part of the editorial team responsible for the publication of *Art as Metaphor* (2007) (Fig. 3). Recently, George has published (with the late Andrew Townsend) *Decoding Neolithic Atlantic and Mediterranean Islands* (2016).

Nationalism and Archaeology

Margarita Díaz-Andreu
Departament de Prehistòria, H. Antiga i Arqueologia, Facultat de Geografia i Història Universitat de Barcelona, ICREA-University of Barcelona, Barcelona, Spain

Introduction

Throughout the last two centuries, nationalism has played an increasingly key role in world politics. Scholarship, however, only awoke to its significance and started analysing it after World War II (Kohn 1946), especially from the late 1960s on (Barnard and Mechner 1965; Deutsch 1966; Kedourie 1966; Smith 1976; Hobsbawm 1990). With the exception of a few comments made by early scholars (Myers 1907: 319; Himmelman 1976: 119–130), it has only been in the last few years that archaeologists have come to realise the importance of discussing the effect that nationalism has had on the discipline and the way in which archaeologists interpret the past. In this, as in many other aspects, archaeologists demonstrate that they are citizens of the world and that the experiences they live through influence their professional practice. This upsurge in interest among archaeologists is related to the rise of nationalist movements throughout the world, due to the end of political regimes in countries such as Spain, Yugoslavia and the USSR, in some cases resulting in conflict and the appearance of new nation-states, political changes that archaeologists have personally experienced. National and ethnic identities are often overlapping phenomena, and recent ethnic conflicts, such as those in Jerusalem and India, have also involved nationalistic uses of archaeological remains that archaeologists have had to deal with. Ethnic conflicts are also behind political claims of indigenous communities throughout the world; these are having a profound effect on the practice of archaeology in an increasing number of countries, leading to a transformation in the definition of archaeology and a change in what it means to be an archaeologist.

Definition

Nationalism is a doctrine that holds that 'humanity is naturally divided into nations, that nations are known by certain characteristics which can be ascertained, and that the only legitimate type of government is national self-government' (Kedourie 1993: 1). For the last two decades, however, many scholars have emphasised the constructivist nature of the nation, arguing that nations do not have an objective existence. Nations are imagined communities (cf. Anderson 1991), whose individuals see themselves as bound together by their culture, history, and common ancestry. Archaeology's potential to provide the nation with information about these ties, especially where history is not able to do this, makes this discipline important in the eyes of the nation.

It is now broadly accepted that archaeology is one of a range of disciplines that feeds national history and national identity. National history needs a past and its drafting usually takes the form, for the earliest periods, of a discrete number of archaeological cultures that are then identified with a particular ethnic group considered to be the origin of the modern inhabitants of the nation. Territory, politics and ethnicity are thus intertwined. Migration and adaptation are often the mechanisms used to explain changes in material culture over time, together with, in many cases, the arrival in the area of new ethnic groups that are also integrated into the national history in some capacity (either as new members of the nation or as its foes). Therefore, national narratives need archaeology, but they also need other disciplines such as history, philology and anthropology. Depending on the way in which the nation is described, some of these disciplines will have more importance than others. Thus, philology is highly considered and subsidised in countries where the national language is key to national identity. Archaeology has a high status in countries where archaeologists provide a wealth of data to describe a nation's Golden Age; Italy and Mexico with their Roman and Aztec pasts are good examples of this. However, although archaeology may not be able to provide such highly esteemed data to explain national identity in other areas of

the world, the information from archaeologists is still useful for writing the nation's history, and this explains the global presence of archaeologists in every country. Their role as data providers for writing the record of the national past is still needed, as national history is not a static narrative, but one that needs to be continuously negotiated and recreated. What it means to be a Canadian or an Australian today is different from what it meant only half a century ago. This explains the continuing importance of archaeology, and how the past of these countries is understood has moved on from the narrative held decades ago. With their practice, archaeologists have been active creators of national identity everywhere in the world, and have also provided the information for others to recreate the national past.

Historical Background

The relationship between nationalism and archaeology started with Modernity, i.e., with the creation of the modern state, although there are precedents in the early modern period and before. The word nation derives from Latin and originally referred to a group of people born in the same territory, either a region or a country. It was used as such in the medieval period and found, for example, in English documents in the formula super omnes nationes. We can find a few examples of the use of the classical past in the medieval period, such as the selection of classical themes to decorate Charlemagne's coffin. However, the main language at the time was that of the Bible. It was during the Renaissance that Europe rediscovered the classical world. The development of urban centres allowed the emergence of a new group in society formed by merchants and traders and a growth in the economic power of the nobility and the monarchy. All these groups needed new forms of political self-definition and new ways of expressing power that would symbolically separate the rulers from the religious medieval discourse, and this was achieved through the language and imagery of Antiquity. Thus, the Roman dictator Cola di Rienzo (c. 1313–1354) legitimised a newly created Roman Republic with the use of the recently discovered fragmentary copy of Vespasian's Lex de Imperio from the first century. This was probably the first time, but by no means the last, that an archaeological object was used to claim political rights in the early modern age.

The concept of the state accepted in Modernity came to be in the early modern era: the use of vernacular languages, the monetisation of the economy, and the decline of the three-order society (peasantry, nobility and clergy). The classical past became one of the main forms of expressing power, and classical antiquities were thus turned into political and social assets. This explains the excavations undertaken from the sixteenth century on in those countries where the Roman Empire had been present, and the collections of antiquities gathered in cabinets of curiosities. It also explains how in the political revolutions of the last third of the eighteenth century, the past appropriated was that of the Classical Civilisations – mainly Rome, but also Greece and Egypt. The idea of the Classical was associated with all that was right, good and useful, and the newly self-defined nations felt confident in considering themselves the true inheritors of Classical Greece and Rome. In this, as in everything else in these first decades of nationalism, the realities on the ground show that there are no clear-cut features that completely separate the onset of the political use of archaeology from the previous period.

The term 'civic nationalism' (also confusingly known as 'political nationalism') has been used by scholars of nationalism to refer to the earliest type of nationalism, characterised by an understanding of individuals as political beings whose self-fulfilment was linked to citizenship and patriotism. The frequent links between these and the Classical past explains the importance given to antiquities in the first museum opened for the enjoyment and enlightenment of a nation – the Louvre, the transfer of antiquities from Rome to Paris during the Napoleonic occupation of Rome, and the inclusion of an antiquarian on the Commission of Sciences and Arts sent to Egypt to learn about the country. The importance of the past – and in particular, the spectacular

monumental remains left behind by ancient civilizations – was also paramount in the earliest nationalist uprisings, when the presence of remains in the territory that were linked to vanished great civilisations was used to justify the national character of the revolutionaries both in Greece and the Spanish Latin American colonies.

However, the character of nationalism changed in the 1840s, and this had a profound effect on the main interests driving the search for antiquities. The task scholars undertook in rationalising cultural and national difference came together with an increasing importance given to language and race in defining the nation. Experts in the study of nationalism have designated this new phenomenon as "mystical" nationalism and, more recently, "cultural" or "ethnic" nationalism. In ethnic or cultural nationalism, nations are defined as units formed by individuals who share a common history and, therefore, form part of the same ethnic group – or, in nineteenth-century parlance, race – speak the same language, and share a distinctive set of customs or culture. A series of new disciplines were professionalised at the time in connection with the new definition of nationalism: first philology and then, in the middle decades of the century, physical anthropology. At the time, the assumption was that the concept of nation was objective and unproblematic, and therefore most believed that there was a direct correspondence between language, race and nation, or, as the latter became increasingly known, culture.

Unsurprisingly, the transformation of the meaning of nation and nationalism from civic to cultural nationalism influenced the study of the archaeological past. The national past became not only that of the Classical civilisations (associated with the ideas of the Good, the Rational and the Truth), but also increasingly that of the groups who had actually lived in the country. In Europe, this led to the social recognition of enquiries about the prehistoric and medieval pasts. For the periods in which no documents existed, the groups inhabiting the national territory were identified by scholars on the basis of the information provided both by the Bible and the Classical sources. It became increasingly clear that the professionalization of the teaching of national prehistoric and medieval archaeology was needed; however, although some posts were created in universities and similar learning bodies, this would mainly have to wait until the twentieth century. In universities and museums, it was more common to find specialists in the archaeology of the ancient Classical civilisations. Beyond Europe racism affected archaeology in two ways. On the one hand, monuments produced by ancient civilisations were considered to have been made by lesser races, and in comparison to the always superior Classical model, they were deemed inferior. On the other hand, where no monuments existed, the indigenous populations living in the area were considered to be a suitable source of information about the prehistoric times. The increasing importance of imperialism as an accurate method of considering a nation's success only exacerbated these trends. Yet, it was in this period that the first local archaeologists started to work on the archaeology of the colonial and imperial areas with no tradition of Western antiquarianism; countries such as India, Indonesia, Egypt and the Ottoman empire. They had to overcome many difficulties to be accepted as members of the profession and to have their opinions heard, not least because of the obstacles created by their fellow imperial colleagues.

After World War I, nationalism became universally accepted as the proper political method for legitimising the political division of the world into sovereign states. In archaeology, this translated into a definite interest in archaeological cultures and ethnogenesis, the latter being the search for the origin of a single ethnic group that characterised the nation, or that of the mixing of many different ethnic groups (see the concept of mestizaje in much of Latin America). It also translated into further growth in the institutionalisation of archaeology, with the creation of more museums, university chairs in archaeology, in which prehistoric and medieval archaeology had an increasing presence, and a generalisation of heritage offices in a rising number of countries. The instability created by the agreements drafted at the close of World War I, however, led to a crisis in democracy and the emergence of extreme

nationalism, especially in Europe. The practice of archaeology reflected this, particularly in countries where the Golden Ages of the nation were able to benefit from archaeologists' work. On the one hand, the number of jobs increased significantly. Examples of this in Europe are an explosion in the number of departments of Prehistory in Germany, and also the increase in funding for Roman archaeology in Italy. On the other hand, this came together with an imbalance in the archaeological periods for which the state was prepared to fund research, resulting in prioritising work on the periods and types of data that justified political narratives. Unfortunately, as happened at excavations such as the Ara Pacis and the Ostia harbour in Italy, the search for immediate results compromised the quality of the work. The political support for racism also led to an increase in archaeology interpreted racially in order to fit contemporary politics. The potentially harmful effects of state funding were a matter of debate in countries such as Britain that were still clutching to democratic regimes, and was reflected, for example, in the conference on 'The Future of Archaeology' held in London in 1943.

The end of World War II soon meant the division of the world into two blocks, in what became known as the Cold War. The state of political affairs affected archaeology in many ways. On the western side of the Iron Curtain, most countries in Europe and America went through a period of apolitisation, partly as a reaction to the previous abuses and to a genuine desire for scientific objectivity. However, in countries such as the US, the McCarthy era had a chilling effect on any political leanings archaeologists may have had. There, rather than being a choice, apolitisation became a self-enforced practice. To the east of the Iron Curtain, archaeology was used under Soviet nationalism to legitimise the political regimes with a generalisation of ethnogenetic studies. In the developing world, the decolonisation of countries, including many in Africa, led to a process of nation-building that had an impact not only on the use of archaeology to create a national past for the new nation, but also on its institutionalisation. A similar process has occurred since the dismembering of the Soviet Union in 1991.

Key Issues and Future Directions

In addition to the nationalisation of the archaeological past going on in the new nation-states, an alternative process has been taking place among indigenous peoples around the globe. To a great degree, this is a movement that can be equated with nationalism. In the United States, the civil rights movement of the mid-1950s raised awareness of the rights Native Americans should have. The American Indian Movement (AIM) was formally founded in 1968 and actions quickly began against archaeologists and physical anthropologists. Their claims were soon heard in other English-speaking areas of the world, and demands to control their past also started in these areas. The demands of indigenous peoples led to legislation such as NAGPRA in the US in 1990 and the Mabo decision of the Australian High Court in 1992, recognising native title to lands in Australia. In addition, there has been a movement for the return of cultural property held in museums to indigenous populations and the repatriation of human remains. The repatriation of antiquities is also being sought by sovereign states on the basis that they were illegally removed from those countries. Examples of this are Greece's request for the return of Elgin Marbles and Guatemala's demand for the Boston Museum of Fine Arts to return the Landon T. Clay collection of Mayan antiquities. The new climate created by these claims and the successes in defying the priority given so far to members of the archaeological profession to rule on everything related to the physical remains of the past has led to new petitions by other communities. These include those from local communities in Europe and elsewhere over the archaeological remains found in their own parish or province, and other faith-based communities such as Hindus, modern re-created beliefs such as Druids, and gender-based movements such as the Mother Goddess movement. The challenges created by all these competing claims to the past are having a profound effect on the makeup of archaeological practice.

Most current debates on the relationship between nationalism and archaeology assess archaeology's potential for nationalist manipulation (Kohl and Fawcett 1995; Atkinson et al. 1996;

Díaz-Andreu and Champion 1996; Silberman and Small 1997; Meskell 1998; Díaz-Andreu 2007; Kohl et al. 2007). Most of the studies of nationalism and archaeology of this kind have looked into particular case studies, and there is an increasingly bulky literature on the subject. The challenges facing archaeology today have also led to a flurry of discussion meetings and publications (Gathercole and Lowenthal 1990; Barkan and Bush 2002; Wylie 2005; Brunk and Young 2009). One of the latter trends regarding studies of the relationship between nationalism and archaeology relates to some recent studies that have paid attention to the commodification of the past and the national marketing of heritage (Rowan and Baram 2004; Pomeroy-Kellinger and Scott 2007).

There are several theoretical discussions in which archaeologists looking at the influence of nationalism on their discipline could engage more widely. One of them is the idea of banal nationalism. Billig (1995) analyses how individuals internalise their national identity so that they perceive themselves as members of the nation even if they are not explicitly reminded of it. It is possible to argue that archaeology is potentially a part of the routine of the national forms and symbols that allow the transformation of nationalism into national identity. Archaeological symbols on coins, such as the owl of Athena on Greek one-euro coins or the Pharaoh's bust on Egyptian one-pound coins, help to reproduce the nation. Archaeological practice also has nationhood continually in its background. The productions of the archaeological profession – national conferences, the language used in publications, and the territory covered in journals and books – are daily reminders of national identity.

Nationalism and Archaeology: Overview

Victor Shnirelman
Institute of Ethnology and Anthropology, Moscow, Russia

State of Knowledge and Current Debates

Introduction

Nationalism is an ideology and social practice which makes the "nation" the major political agent and privileges national interests over all the others. In relation to incorporation rules, scholars distinguish between civic nationalism (inclusive) which embraces all people having citizenship and ethnic nationalism (exclusive) which selects people depending on their origins (on the principle of "blood" which usually emphasizes ethnic origins through paternal or maternal lines or both). With reference to goals, one can distinguish between political, economic, and cultural nationalisms. Nationalism usually (although not always) refers to shared language and culture, their continuity in time, and ethnic roots in a given geographical area. Imagination and emotions play an important role in the development of these ideas. An image of a cohesive and rooted community serves to legitimate a nation's claims for sovereignty within a well-bounded territory. All these images and ideas need to be supported with solid scholarly arguments including references to the traces of the ancestors' activity materialized in historical and archaeological sites and monuments.

It can also be argued that nationalism served to enhance archaeology's professionalization in many areas as well as further its institutionalization. This is because archaeology has been used in numerous instances to claim a nation's long continuity in time through its rich past and ancient roots. For this goal an essentialist approach has often been exploited – one which reifies the nation in order to increase national consolidation. This approach has obtained a new direction under globalization of which by-products have been localization and a passion for local identities. As a result, the role of "ethnic nationalism" has evolved and become more complex. The struggle for recognition has intensified in many places, and cultural heritage claims have become an important social symbol legitimizing political and cultural assertions for many groups. Some crucial questions arise from these concepts however such as what is included or excluded from a "national heritage"? and whose heritage is it that is being privileged?

Archaeology for Nationalism

Archaeology is valued by those wishing to use it for nationalistic purposes for its ability to provide material evidence of long cultural continuity and to establish links with remote ancestors. Even recent newcomers can be fascinated with their predecessors' achievements in the remote past (e.g., Neolithic shrines are considered national treasury in Malta; see Fig. 1). A presentation of the ancestors' advancements (e.g., various inventions, monument buildings, writing, or a formation of state) including discoveries of new lands plays a great positive role. All of these images may provide psychological comfort and foster self-respect. In addition, the remembrance of glorious ancestors may also be used by people who have experienced historical trauma (e.g., colonial suppression, discrimination, ethnic cleansings, and especially genocide).

Even in cases where ancestors may have suffered defeats, an idea of heroism and sacrifice for the sake of people's freedom may still be valued. Material evidence of such feats (e.g., Masada in Israel – see Fig. 2, Numancia in Spain, and Alésia in France) become national holy places and sites

Nationalism and Archaeology: Overview, Fig. 2 Masada, Israel. (Author's photo)

of pilgrimage and respect. All this may assist in the struggle for national independence and sovereignty as well as the building or restoration of a national state. Archaeological findings can also serve as markers of national territory and be used as national symbols (e.g., the state emblem of the Republic of Sakha – see Fig. 3). In addition, special museums may be established to respect ancestors and be illuminated by archaeological findings and discoveries (e.g., as in the case of the Museum of the Yayoi culture, Osaka, Japan – see Fig. 4). Monuments of national glory can also

be designed using archaeological prototypes (as in the case of Almaty, Kazakhstan – see Fig. 5). Archaeological artifacts too can be represented in national decorations, design elements, and national costume as well as in art, theater, and cinema. Sometimes they are depicted on banknotes and coins, postcards, and stamps and used in advertisements (e.g., Aztec Templo Mayor on Mexican coins; the lur, the sun-wagon, and the "Golden Horns" on Danish coins; a Chalcolithic pot from Vuchedol on the Croatian banknote; the Saka warrior on the Kazakhstan banknote – Fig. 6). Newly established ethnic (pagan) religions (i.e., neo-pagan religions being a segment of the New Age religiosity) encourage worship of grave mounds, dolmens, and ancient stone idols. Some archaeological sites have also become centers of worship and places of pilgrimage (e.g., Stonehenge in England, the Bronze Age site of Arkaim in the Southern Urals – see Fig. 7 – or the medieval town of Bulgar in Tatarstan). All these manifestations and developments are encouraged by a nationalism aspiring to strengthen its positions with references to the remote past.

Nationalism and Archaeology: Overview, Fig. 3 The state emblem of the Republic of Sakha. (Author's photo)

A view of the past is commonly exploited by the state as the key symbolic resource to claim the given territory and to establish its borders, as well as for territorial expansion, struggle for spheres of interests, legitimation of power in general, and colonial rule in particular. At the same time the colonial and Indigenous peoples refer to the remote past to claim their right for independence (this was characteristic in colonial times – e.g., for the Indian nationalists who glorified the Aryans and for the Black African leaders in South Rhodesia who referred to the Great Zimbabwe – and also in certain federal multicultural states, e.g., in the USSR where the Armenians were searching for their ancestors in the state of Urartu). Thus, archaeology is used for ideological struggle and propaganda by various actors in different contexts (Fowler 1987; MacDonald et al. 1995). Nazi Germany provides us with the most evident and tragic case when the

nation's claims were approved with reference to the "race" theory including the Nazi interpretation of archaeological data (Härke 2000).

It is not only states that may strive to present a positive view of the past but also societies as well as particular social and cultural groups. Indeed, icons of social memory can serve as a basis for sovereignty and encourage national self-awareness and self-respect.

Social Context of Archaeology, and Nationalism

Thus, archaeology develops and is used in various social and political contexts serving several functions and with various goals. This is precisely why Bruce Trigger distinguished between nationalist, colonialist, and imperialist (world-oriented) archaeology. Being somewhat arbitrary, the scheme is based on the idea that "archaeology does not function independently of the societies in which it is practiced" (Trigger 1984). Trigger associated the very emergence of prehistoric archaeology in Europe with the interests of the middle class which, on the one hand, were the bearer of the idea of progress yet, on the other, shared ideas of romanticism encouraged by nationalism, especially after the Napoleonic period (Trigger 1989). Thus, nationalism provided archaeology with important social and political functions.

At the same time, archaeology also affected nationalism by focusing on autochthonous origins, long national genealogy, and rigid boundaries of ethnic territories. Nationalism also encourages a view of archaeological culture as a material manifestation of an ethnic group. This assists in the acquiring of remote ancestors and providing the myth of a "golden age" with its desired materiality. Ancient finds that can be associated with the idea of "originality" can play an important role in establishing these views and can also become symbols of national identity. Illustrations of this point include the Celtic cross and Celtic decorations in Ireland; the lur, the sun-wagon, and the "Golden Horns" in Denmark; the "Venetian horse" in Slovenia; and the Persian rhytons in Kazakhstan.

Archaeology is represented in various countries by distinct "national traditions," is structured differently depending on the political agenda, and can play various political roles. Philip Kohl distinguishes between two models which associate nationalism with archaeology in their own ways: (a) in the way nations have been built up by immigrants or shaped by their miscegenation with Indigenous peoples and (b) the way that

Nationalism and Archaeology: Overview, Fig. 7 Pilgrims in Arkaim, the Southern Urals, Russia. (Author's photo)

nations have been shaped after a collapse of colonialism (Kohl 1998: 233). He also notes that even spatially distant Near Eastern archaeology was very important for the national prestige of the world powers.

One can reveal variability in terms of not only space but also time. For example, according to Margarita Diaz-Andreu, the past was used and even viewed quite differently at the time of civic nationalism's domination (1789–1860s) and later on after the emergence of ethnic nationalism. Scholars became aware of the links between archaeology and history only by the very late nineteenth century after the unification of Italy and Germany (Diaz-Andreu 2007). In addition, at that time archaeology was greatly affected by colonial views and "racial" ideas became popular in that context.

Dominant ideologies play a crucial role in shaping the view of ancestors. Indeed, before the growth of ethnic nationalism, European nationalists neglected an idea of rootedness in the soil and highly valued ancestors that arrived from elsewhere bringing with them products of "civilization." For example, in the nineteenth century, the British preferred intruding Anglo-Saxons and even Phoenicians as ancestors rather than the Indigenous Britons.

In the nineteenth century, European romantic nationalism encouraged archaeology to study the past of the peoples, some of whom made up majorities in the well-established states (e.g., in Denmark) and others who were the minorities who struggled for civil rights and sometimes aspired to have their own state (e.g., Czechs). Dominant majorities and minorities used the same approaches to interpret the remote past yet developed different views of the past to achieve different goals. In particular the culture-historical approach in archaeology was used in this regard. In due course, archaeological cultures began to be viewed as the material remains of ancient ethnic groups. A theoretical foundation for this approach was developed by G. Kossinna who was followed by V. Gordon Childe (Trigger 1989: 161–173). The cultures' dynamics (evolution, territorial expansion, area shrinkage, and disappearance) were uncritically viewed as a real history of distinct ancient ethnic groups. This simplified and one-dimensional approach has been strongly criticized and revised during the last 20–30 years.

Views of the Past, Archaeology, and Nation-Building

In due course, the issue of whose ancestors were represented by particular archaeological cultures

became a sensitive topic. The past proved to be a contested field which permanently accompanied a struggle for national self-determination. In this context, archaeology has been extensively utilized by minorities who did not have written traditions. In any event, archaeology has provided arguments for national pride for ancestors who were associated with creativity and outstanding achievements. It also became less necessary to search for European ancestry beyond the borders of Europe. Thus, by the end of the nineteenth century Germans, for example, began to locate ancient "Aryans" in Northern Europe as though they spread out from there throughout the world.

Yet, because of colonial politics, the Near East was still viewed in the nineteenth century as the "cradle of the Western civilization," and this interpretation was supported by Biblical traditions (Silberman 1989). In the eighteenth and nineteenth centuries, British and French colonialism, which was interested in control of the past of subjugated peoples, encouraged a view of civilization movement Ex Oriente Lux. This demand was met by researchers studying Biblical archaeology in their search for material traces of the Biblical record through their attempts to prove the Christian beliefs that underpinned the identities of many Europeans.

While discovering the roots of contemporary peoples, nationalist archaeologists contributed to contemporary nation-building. As already noted, nationalist archaeology reached its climax in Nazi Germany. In the late twentieth century nationalist archaeological approaches suffered a decline in Western and Central Europe but were on the rise in Eastern Europe due to the decline and then the collapse of communism which was finally replaced with nationalism. An emergence of the EU encouraged public interest in the common Celtic substratum which was met in the 1980s and 1990s by a number of exhibitions focused on the Early Iron Age as though it witnessed the initial forms of European unity (e.g., exhibitions such as "Celts – The Roots of Europe" in Venice in 1991 and "Mysteries of the Celts" in Frankfurt-on-Main in 2002).

Whereas some nations developed their views of the glorious past in the course of territorial and political expansion (e.g., Great Britain and France at the epoch of colonial empires), others did so while losing their former territories as their national borders shrank (e.g., Denmark in the nineteenth century). Some countries (such as Russia-USSR and Yugoslavia) experienced both developments in different periods of their history. These cases demonstrate how the same archaeological data receive different treatment and interpretation depending on the political environment (Shnirelman 2005). Until recently a struggle for "heritage" was aimed at overcoming colonial residues and was perceived as "postcolonial resistance." However, nowadays it is often waged between young nations arising out of colonial pasts or aimed against local minorities. While minorities have in recent times spoken from the margins in many countries, their status has been changing and they may now speak from a more authoritative position in some instances.

According to Trigger, "colonial archaeology" developed in the states built up by "white" immigrants (e.g., USA, Canada, Australia, and New Zealand). The newcomers viewed local people as "primitive" with static cultures, and if their culture was perceived to have changed over time, then this was seen as a result of external influences. This view served to legitimate European rule as a civilizing mission. The historical heritage of Indigenous peoples was also appropriated by the newcomers. Thus, Cecil Rhodes believed that Great Zimbabwe in the former South Rhodesia was originally inhabited by the Phoenicians and "white" Americans ascribed the Ohio mounds to some "superior race" (Silverberg 1968).

The nationalism of younger nations has also drastically affected the strategies and focus of regional archaeologies. Until recently the Paleolithic was the core issue in Sub-Saharan Africa where foreign archaeologists were searching for human ancestors; the Early Iron Age was less known because it had nothing to do with the "white man's past." The Africans' creativity was denied, and "whites" were less interested in their past. The "native" Early Iron Age archaeology began developing only under independence. Likewise, in British India, colonial archaeologists were interested only in the Indo-European

antiquities and Harappan civilization, the latter being associated with intruders. A "native" archaeology focused on local cultures developed only in independent India and Pakistan. It is in this way that colonial archaeology turned into a nationalist one. Yet, even before independence, the discoveries of Indian antiquities encouraged a growth of both national self-awareness and local nationalism. Nonetheless, prehistory was still privileged in independent India in contrast to the medieval period dominated by Islam. Nowadays archaeological data are often used by Hindu radicals to prove allegedly autochthonous origins of the Aryans. India serves a case where under radical Hinduism, some archaeologists reject secular nationalism in favor of religious views of the past (Ratnagar 2007).

Sometimes nationalism encourages extreme autochthonism. There are cases where the earliest remains of *Homo* species having been discovered in the territory of a contemporary state has become a point of pride and has been associated with the beginning of continuous human evolution up to the contemporary population. Thus, the *Homo erectus* remains from the Azykh cave in Azerbaijan were advertised as the "first Azerbaijani," the *Homo erectus* find from Dmanisi in Georgia was associated with the "first European," and remains of the early primates in Myanmar were announced as the forefathers of the humanity. In the first case, one deals with national claims for territory (the Azykh cave is situated in the Nagorny Karabakh), in the second case with an aspiration to be included into the EU, and in the third case with the fosterage of patriotism and self-respect in one of the poorest countries in the world.

Indigenous peoples usually appreciate more moderate views of the past presenting the given region as being populated long before colonization – this ensures that they are able to build up their life without intervention from outside as their remote ancestors did (Spriggs 1999: 120). For example, in response to a colonial view introduced by the Chinese and French, which exaggerated the role of the intruders, under independence, Vietnamese archaeologists argued that higher cultures flourished long before the Chinese arrived. This archaeology was a salve for the trauma caused by the long struggle for independence. A restoration of the devastated country demanded for a memory of the local ancient state that developed before Chinese occupation.

Nowadays, many Western archaeologists quite consciously support minority groups while confirming their claims for local natural resources and even political autonomy with a reference to archaeological data and the concept of autochthonism.

Nationalists make a choice between various explanatory models depending on political agendas. The migratory model is popular in case of territorial expansion and an autochthonous one in cases where territorial sovereignty has been gained or where there has been territorial shrinkage. The first model was common for colonial or expansionist powers. Imperialism encouraged migration models which were used to discover the early ancestors' resettlements and their occupation of the vast lands as a civilizing mission of the "white people," "children of the Sun" (G. Elliot-Smith), or "Indo-Germans" (G. Kossinna). Colonial and imperialist archaeology welcomed "racial" ideas which explained sociocultural development with a reference to biology (Trigger 1989: 111–138). For example, a view of the German master race was developed by Kossinna which was appreciated by the Nazis.

The nationalist archaeology in Turkey after 1923 is a clear case of the second model. To legitimate itself, the new state has emphasized an autochthonism in which views of the past incorporated the entire cultural heritage of Asia Minor including the pre-Islamic period. As a result Islamic archaeology is less developed in Turkey even today. Likewise, to legitimate his power in Iran, Reza Pahlavi paid great attention to the glorification of a pre-Islamic past and supported the restoration of early traditions associated with Zoroastrianism.

Sometimes new states appreciate a view of ancestors-invaders who were associated with military glory or a civilizing mission (e.g., the early Magyars in Hungary – Fig. 8, or the Scythians in Ossetia). In addition, during a struggle for independence and/or after victory, nationalists can

Nationalism and Archaeology: Overview, Fig. 8 A celebration of the 1100th anniversary of the ancestors' arrival to Hungary (Budapest 1996). (Author's photo)

interpret the same archaeological data in different ways. For example, under British rule, Indian nationalists appreciated the Aryans' arrival from elsewhere, yet after India gained independence, they began to present Northern India as a cradle of the Aryans.

Indeed, the autochthonous model fits nationalist agendas better than migration theories. This is because such models meet the demand for a view of the ancestors' independent development and high cultural achievements in the given territory. In some cases, external influences are entirely denied and suggestions of diffusion or migration are treated as survivals of a colonial mentality. Material evidence of influences can thus be ignored and hidden from outsiders. For example, about 20 years ago, the Chinese authorities temporarily denied access to foreign archaeologists to the remarkable finds in Xinjiang, where rich graves with Caucasian skeletons were discovered dating to the late second mill. BCE, and Korean scholars and tourists were not allowed access to Northeast China where the early Korean state of Koguryo was situated in the past.

When external impacts are accepted, local archaeologists sometimes make a case for such influences as arriving without the involvement of the neighboring state which practiced colonial rule until recently. For example, for some time, Irish archaeologists viewed the dolmen culture as having arrived from the Mediterranean area (circumventing England) and Korean archaeologists have at times argued that bronze technology arrived from Mesopotamia rather than through China.

Sometimes conflicting interests cause confusion – an idea of "originality" demands for particular ancestors, but political alliances need common ancestors to make allies closer to each other. Political unification encourages a view of common ancestors (as in the reference to the Celtic past in the EU – see above), although particular polities appreciated views of different ancestors in the former time.

Being based on rigid centralization, authoritarian and totalitarian regimes aspire to develop a view of cultural homogeneity in the past (e.g., the Celtic idea in Spain under Franco, the image of the Roman Empire in Italy under Mussolini, and the view of Gauls in France under the Vichy). In contrast, liberal rule, through an emphasis on cultural plurality, encourages a view of the past that privileges cultural heterogeneity. For example, in Great Britain the mixing of different groups and cultures in the past (e.g., Britons, Anglo-Saxons, Romans, and Normans) was seen to have predetermined the viability of the current nation and its ability for colonial expansion.

In the USSR, a view of cultural heterogeneity was accepted only in combination with the ideas of the state-shaping role of ethnic Russians as well as the leading role of titled peoples in the national

republics in remote times. State centralization was based on rigid ethnic hierarchy which determined a view of the past. In some cases this model resulted in an appropriation of the minorities' past by dominant majorities (e.g., in China and Japan).

In culturally heterogeneous societies, the dominant majority sometimes uses views of the past for legitimating its domination, whereas minorities may use archaeology for claims relating to equality or political sovereignty. In the first case, majorities may be searching for remote ancestors at the given territory – for example, attempts of certain "whites" to find traces of ancient transatlantic migrations and to ascribe the Native American antiquities to intruders from Europe and North Africa or, at least, from the area of some so-called "higher" civilizations. In some circumstances, fakes have even been employed to achieve these goals. To defend their human rights and to resist discrimination, minorities may use the same resources: either by searching for their autochthonous origins or by attempting to trace their ancestors' migrations to the new territory (e.g., the "Black Celts" in Great Britain or "Ancient Egyptians" in the New World).

It should also be remembered that the interpretation of the past is affected by the investigator's political views. A military victory over the Arabs in 1948 encouraged the Israeli general-archaeologist Yigael Yadin to treat an Israelite resettlement to the Promised Land as a conquest, whereas the Left Zionist Yohanan Aharoni viewed this as a slow peaceful infiltration. It also affected the choices of archaeological sites investigated by the archaeologists. Whereas Yadin focused on excavations of the Canaanite city of Hazor (which was destroyed at the eve of the Early Iron Age), Aharoni searched for the early Israelite settlements in the Galilee hills (Abu el-Haj 2001: 99–116).

Nationalism can even affect field methods. Indeed, some archaeologists, when in search of nationally important material evidence, have destroyed upper layers without employing standard recording techniques or have neglected the small finds that illuminate everyday life in the past in favor of large monumental constructions of "national significance." Thus, in some cases, nationally "sensitive" findings are privileged at the expense of what "has no importance" (Abu el-Haj 2001: 148–158).

One has also to distinguish between "native archaeology" and "archaeology abroad." The former focuses on the search for one's own ancestors and the restoration of a long genealogy. This type of archaeology is also often more emotional. Such archaeology is based on ethnic nationalism which is characteristic for Eastern and South-Eastern European countries and was encouraged in the former USSR where ethnicity was institutionalized. The latter calls for "objectivity" and scientism and can ignore the emotions of the local inhabitants. It is a stepchild of imperialism, and it is here that evolutionary approaches have been utilized (Trigger 1989). Noteworthy, this approach has been characteristic not only in Western archaeology but also in Soviet archaeology represented in the core – in Moscow and Leningrad (by contrast to archaeology in particular republics).

Certain authors make a distinction between national and nationalist archaeology: the former deals with archaeological investigations within the national state, and the latter is sensitive to political blueprints mobilizing archaeology to take part in nation-building and the shaping of national identity (Kohl 1998: 226 – see also Trigger 1989). At the same time, archaeology played various roles in this process in different countries, and its evaluation is a matter for discussion. Indeed, whereas in some countries national pride focused on Paleolithic archaeology (e.g., in France), in others the archaeology of the Neolithic and Bronze Ages was highlighted (e.g., in Scandinavia). Sometimes the emphasis changed over time as occurred in Germany (e.g., from philhellenism to primordial Germanic tribes). This change reflected the unification of Germany and a growth of German nationalism and chauvinism (Arnold and Hassman 1995; Marchand 1996; Härke 2000).

Archaeology and Politics

The abovementioned case studies serve to illuminate the fact that views about the past are highly

dependent on political factors which affect archaeology as well. This means that archaeology can hardly be considered as "value-free research." Archaeologists can be just as affected by social stances as can the amateurs and politicians who may also use views of the past to serve their own causes. In choosing a field or an object of study or by giving names to archaeological cultures, classifying data, restoring genealogies, and establishing borders, archaeology is also an active political agent.

At the same time we should be careful to distinguish that while on the one hand archaeology is a professional activity with its own theory, methodology, and ethical code, on the other its products can be used by amateurs and politicians. One should also distinguish between cases where archaeological knowledge is used for political purposes as opposed to an archaeologists' active participation in national movements.

For example, there were many colonial and military officials who developed "racial" doctrine. And in some new independent states, archaeologists have often shared nationalist ideologies which have affected their professional activities. In Bulgaria, for example, archaeologists, as custodians of the national past, actively participated in politics and occupied important state positions. In Israel well-known politicians and military officers were among the first archaeologists. In Myanmar, members of the military government actively participated in the search for "early humans" in the 1990s.

Sometimes archaeologists may purposely attempt to avoid politics (e.g., in Ireland and Japan), yet their discoveries may still be used to serve political ends. In Southern Rhodesia, archaeology was strictly controlled by colonial officials. At the same time, African revolutionaries used archaeological knowledge to further their own interests. In Iran, Shah Reza Pahlavi and his successor Mohammad Reza Shah paid great attention to history and encouraged archaeological investigations as they found a basis for patriotism in the achievements of ancient Iranian kings. In contemporary India, some archaeologists willingly serve Hindu politics. To put it briefly, in various countries, professional archaeology has complicated relationships with nationalist movements.

In any case, archaeological results depend not only on scholarly methodology but also on external social factors. Moreover, today a "folk archaeology" may develop in conjunction with professional archaeology and is based on non-scholarly (or pseudo-scholarly) views. This new type of archaeology may offer its own interpretation of well-known archaeological discoveries and/or make forgeries. This type of archaeology develops nationalist, "racial," or religious ideas (New Age style).

Nationalism Against Archaeology

The relationships between nationalism and archaeology are not without problems. There is an ambivalent attitude towards archaeology in the former colonies, and it is often by no means positive. In many Arab countries, it is an "elite knowledge" which is far from ordinary people who share prejudices about the pre-Islamic past. Negative feelings against archaeology in the Arab countries of the Middle East were also provoked by its long association with colonial rule. One can observe the same attitudes among Indigenous Australians.

In Africa, while using contemporary ethnic names in their reconstructions of the regional past, the "white" archaeologists unconsciously provoked ethnic separatism and, thus, undermined the nation-state. As a result, suspicion has ensued. The "white" settlers also were threatened by archaeologists whose presentations of the past inspired "black" movements. On their side, while coming to power, "black" leaders called into question the ability of "whites" to provide objective interpretations about the past.

In some cases, new archaeological studies and interpretations contradict the views of the past developed under a local nationalism and informed by oral traditions. In addition, the meaning of local sites for archaeologists and Indigenous peoples can differ greatly. Indeed, archaeologists may simply view the sites as objects of scholarly interest, whereas local people may respect them as sacred places.

Nationalism can also hinder the archaeological study of some sites and periods. Indeed, ethnic nationalism focuses on the search for its own ancestors; the "others" are either ignored or treated as enemies. In the latter case, their achievements may be downplayed or archaeological studies about such groups may be hindered or even prohibited by the authorities. Examples of such situations include studies of the Golden Horde, Khazar Kaganate, and Scandinavians' (Viking) activity in the early medieval period in the USSR, the Muslim past in Spain and Israel, and Caucasian Bronze Age burials in China. In Egypt, under President Naser, it also became impossible to study the Aramaic ward on Elephantine Island where the Jewish garrison was stationed in the fifth century BCE.

The history of archaeology has witnessed fierce debates on the ethnic attribution of early sites and early ethnic boundaries. Sometimes this has resulted in the destruction of particular sacred sites and attempts to replace them with some others (e.g., the demolition of Babri Masjid in Ayodhya, India, in 1992). Faked "archaeological data" has even been forged in such instances. In other cases, local sacred places may be owned by several different religious communities, and there is the difficult issue regarding which one has to be maintained and restored first (e.g., Judaic, Christian, and Muslim sites in Israel).

Debates about the ethnic past can also become important components of ideological confrontation resulting in bloody wars. In the course of warfare, early sites and monuments have been purposefully destroyed to erase the memory of the enemies from the local past (such as the recent wars in the Balkans, in Abkhazia, in Chechnya). Sometimes a reinterpretation of the past and religious prohibitions result in the destruction of early sites or archaeological data – e.g., the destruction of ancient statues of Buddha in Bamiyan, Afghanistan, in March 2001, under the Taliban rule as well as all of the Buddha images in the National Museum in Kabul; a decline of interest in the pre-Muslim past in Egypt under Naser; the marginalization of archaeology in Iran after the revolution as "despots' maid"; and the demolition of the mosque in Ayodhya. After 1974 a cleansing of the Greek antiquities took place in the northern (Turkic) part of Cyprus including the looting of archaeological materials, the destruction of medieval churches, and the prohibition of archaeological excavations. Thus, nationalism can both encourage archaeological investigations and result in the destruction of archaeological sites and looting of archaeological treasuries.

Sometimes the dominant religion may demand the "forgetting" of the evidence of other religions (e.g., as in the case of the Russian Empire where archaeologists focused on the Christian sites at the expense of Islam and paganism) – state atheism too has hindered studies of religious aspects of the past (e.g., an ignorance of the Church archaeology in the USSR). Young nations may also occupy themselves with studies of the remote past and ignore the era of recent colonial rule. In the Middle East, local archaeologists have also ignored ruins of the Ottoman period which remind them of the suffering under sultan despotism (Silberman 1989: 231–232). In Ireland, local archaeologists are less interested in studying the period after the Anglo-Norman invasion, whereas in Mexico they focus on the pre-Columbian past at the expense of colonial remains, and in India, local archaeologists ignore medieval sites associated with Muslim rule. All this may reach a climax in "racial" attitudes which are sometimes encouraged and used in a radical nationalism. As a result, some archaeologists have warned us against the usage of archaeological data in contemporary politics (MacDonald et al. 1995).

Archaeology and Ethics

In contemporary archaeological practice, we often attempt to deal with "multiple pasts" – a situation which has raised the issue of the archaeologists' responsibility and role in "shaping identities." This is an especially complex problem in the case of contested territories where neighboring groups struggle for historic heritage and where each side attempts to ascribe local archaeological sites to their own ancestors (Shnirelman 2001, 2006, 2009). While understanding the dangerous nature of such debates, certain scholars discuss the moral responsibilities of archaeologists who, by the results of their studies, support one side and unconsciously or otherwise encourage intergroup

conflicts or separatism (Spriggs 1999: 116–118). Such situations may also result in ideological struggles between archaeologists. Yet this is not a solution because nationalists are interested in political benefits rather than plausible scholarly results. Therefore, archaeologists who follow scholarly methodology are unable to provide them with the desired "truth," and nationalists may simply develop their own interpretations of archaeological data.

As a result, archaeologists today can be faced with the problem of choosing whether or not to be loyal to scholarship or to neglect it in favor of local nationalism or minority rights, and where the latter may be the case, which side to take in a multicultural milieu when different ethnic groups are claiming the same historical resources. Such situations raise significant ethical dilemmas for archaeologists.

Over the last 20–30 years, archaeologists have become increasingly aware of these problems which have resulted in provocative and stimulating discussions which will no doubt continue into the future (Trigger 1984, 1989; Silberman 1989; Kohl and Fawcett 1995; Schmidt and Patterson 1995; Atkinson et al. 1996; Diaz-Andreu and Champion 1996; Kohl 1998; Meskell 1998; Malone and Kaner 1999; Diaz-Andreu 2001, 2007; Kohl et al. 2007).

Nationalism and Politics in Chinese Archaeology

Phillip Grimberg
Department of Chinese Studies, Friedrich-Alexander-University Erlangen-Nuremberg, Erlangen, Germany

Introduction

Although China looks back at a history of more than a thousand years of antiquarian and proto-archaeological studies, modern field archaeology was only introduced to China in the early twentieth century. In a time of rising nationalism, archaeology played a significant role in the (re-) construction of China's national history. The search for the cultural origins of the country became the driving force in the development of the discipline in China, exerting remarkable influence on its theoretical research orientations and interpretations of archaeological finds.

From the very beginning, Chinese archaeology has been indicative of changing social and political paradigms: over the course of the twentieth century the many changes in the political landscape of China from the Republican era (1912–1949) to the years of the rule of Mao Zedong毛泽东 (1893/1949–1976) and the tumultuous decade of the Cultural Revolution (1966–1976) followed by the era of "reform and opening-up" under Deng Xiaoping邓小平 (1978–1997) until today's increasingly nationalist rhetoric, Chinese archaeology always functioned both as an indicator and an instrument of particular social and political agendas. The diverse and ever-changing concepts of nationalism in China along with different state systems (1912–1949/since 1949) and institutional structures heavily influenced the development of Chinese archaeology and resulted in a wide range of approaches to fundamental archaeological problems. The introduction of western field methods in the late 1920s on the one hand, the influence of Marxist ideology since the early 1950s as well as the challenges of internationalization and globalization in recent decades on the other, shaped Chinese archaeology into a social science that closely links material culture with history and its ever-political overtones. While the main objective of Chinese archaeology – the reconstruction of the country's national history and the identification of its cultural origins – remains almost entirely unchanged, new research approaches are being incorporated into the discipline's overall research agenda in recent years, allowing for a more international orientation of the field and the use of state-of-the art methods and technologies (Liu 2017). Politics and nationalism came to play a decisive part in the development and objectives of Chinese archaeology right from the start and – with regard to more recent developments in China's ideological and geopolitical strategy – will likely continue to do so.

Definition

In its most generic form, the concept of archaeology in China – *kaoguxue* 考古学or "investigating

antiquity" in Chinese – is a term borrowed from the title of a catalogue of antiques (*Kaogu tu* 考古图, 1092) by Song (960–1276) scholar Lü Dalin 吕大临 (1046–1092). It was only reintroduced to Chinese scholarly discourse from Japan in the second half of the nineteenth century where it had been adopted for the phenomenon of western field archaeology and describes the scientific study and excavation of material and environmental remains of past human life and activities. However, in modern and contemporary China it is also closely linked to the spheres of nationalism and politics, ultimately aimed at substantiating the principles of historical evolution, and functioning as a tool for the reconstruction of the nation's history as well as an agent for the Marxist theoretical framework of historical materialism (Liu 2017). Over the course of its historical evolution during the Republican era (1912–1949) Chinese nationalism was informed by modernism, progressivism, historical criticism, and social Darwinism, while after the founding of the People's Republic of China in 1949 Marxist worldviews, the concept of Sinocentrism and the doctrine of the cultural and national unity of China proved most influential to Chinese nationalism and – therefore – Chinese nationalist archaeology (Trigger 2006).

Historical Background

1919–1949

Chinese Nationalism and Archaeology During the First Half of the Twentieth Century

Modern field archaeology in China has a history of approximately one hundred years. It was first introduced during the time of the May Fourth Movement (Wusi yundong 五四运动) of 1919. Starting out as a protest against the treaty of Versailles, young Chinese intellectuals and scholars associated with the movement soon adopted Western ideas and embraced new concepts of democracy and science. Caught up amidst heated debates about China's cultural foundations – their past, present, and future – archaeology quickly became entangled with politics (Xia 1979). On the one hand, archaeology was seen as a new approach towards understanding China's historic and prehistoric past and its material remains. On the other hand, archaeology and archaeological finds early on were regarded as a means to reestablish and reinforce a national identity in China that was neither solely based on Western perception of Chinese history nor on traditional Confucian historiography (Chang 1981).

At the turn of the twentieth century, China witnessed a surge in nationalism that was directed against the rule of the Manchu dynasty that invaded the country some 250 years earlier as well as against the geopolitical ambitions of Western colonial powers and growing Japanese aggressions. Political figures of the day like Sun Yat-sen (Jiang Jieshi 蒋介石, 1866–1925) or Liang Qichao 梁启超 (1873–1929) called for a new national consciousness and a Chinese identity based on cultural and historic grounds. This new nationalism, based on notions of heritage and history that were imported to China by foreign-trained members of the intellectual elite, soon gained momentum and became an important political incentive to the development of archaeology in China (Falkenhausen 1995).

Chinese nationalism in the late nineteenth and early twentieth century started out as an ethnocentrically inclined approach, focusing on the Han majority and marginalizing minority groups that were widely expected to integrate themselves and their traditions into the grand narrative of a commonly shared cultural origin (Dikötter 1992). After the founding of the Republic of China in 1912, however, concepts of a multiethnic nationalism started to emerge that stressed national and political unity of the peoples of China (minzu zhi tongyi民族之统一) over ethnical concerns, trying to merge the minorities of the Manchus, the Mongols, the Hui (Huizu回族), and the Tibetans with the Han ethnic majority into the so-called Five-Race Republic (wuzu gonghe 五族共和) as an entity of shared cultural origins and values (Mullaney 2010). Not surprisingly, the century-long oppression of the Han by the Manchu elite had ripple effects on the perception of ethnicity, history, and culture. Nationalistic approaches therefore endorsed archaeology as a means of proving the existence of a common

source of all things quintessentially Chinese. Against this background, the discovery of the Shang oracle bones in 1928 with their inscribed characters that still bore resemblance, albeit it remotely, to the contemporary writing system of China was seen as conclusive evidence of the existence and perpetuation of a set of essential cultural qualities that shaped Chinese society and civilization since antiquity.

The Formative Years of Chinese Archaeology (1928–1949)

The earliest archaeological excavations on Chinese soil took place at the cave site at Zhoukoudian in the vicinity of Beijing. First discovered in 1918, large-scale excavations started in 1928. It was the Swedish geologist Johann Gunnar Andersson (1874–1960) and his Austrian-born assistant Otto Zdansky (1894–1988) who also worked on the remnants of the Shang capital Anyang as well as the remains of the neolithic Yangshao culture in Henan's Yellow River Valley that heralded the beginnings of archaeology in China and prepared the ground for the future.

Zhoukoudian

The excavation of specimens of *Homo erectus*, the so-called Peking man (Beijing yuanren 北京猿人, *Sinanthropus pekinensis*/*Homo erectus pekinensis*), at the site in Zhoukoudian周口店 unearthed some of the oldest human remains found to date, providing the contemporary discourse with palpable proof of the indigenous origins of the (Han) Chinese people, opposing notions of "foreign" traces in the evolution of Chinese civilization and culture that flared up in contemporary scholarly debates, instead pointing to the indigenous genesis of Chinese ethnicity (Gao 2010; Leibold 2006; Jin and Su 2000). The discovery of the Peking man gave an affirmative boost to the contemporary political and scholarly narrative that centered on (Han-Chinese) ethnicity and the origins of Chinese culture and civilization (Liu 2017).

Anyang

In the same year, excavations at Zhoukoudian started, local Chinese archaeology entered its initial stage. In 1928, Harvard trained archaeologist and founding director of the Academia Sinica (Zhonyang yanjiuyuan 中央研究院), the Chinese Institute for History and Philology, Li Ji 李济 (1896–1979) led a team of Chinese archaeologists to work at the site of the ruins of the former Shang capital Yin (Yinxu 殷墟) in modern day Anyang 安阳in Henan province, in an effort to identify China's cultural roots through archaeological methods (Brown 2008). Randomly discovered in 1899 and first excavated by Andersson in 1921, the site yielded large amounts of oracle bones – mainly ox scapulae – and inscribed tortoise shells that represented a direct link to China's cultural origins and the age of the Sage Kings of high antiquity (Bagley 1999). The project in Anyang was the first state-sponsored archaeological excavation in China driven by a strong sense of scientific and technological enthusiasm and a robust nationalism that was regarded as a remedy for China's social and political backwardness by many young scholars and intellectuals of the time (Liu 2017).

The Yangshao Culture

The Yangshao culture (仰韶, ca. 5000–3000 BCE) was named after the place of its first discovery by Andersson in 1921. During his excavations, Andersson's finds of ornately decorated pottery let him to the conclusion that its patterns originated in Central Asia or even in the Near East rather than in the Central Plains of China, providing first evidence of a diffusion of cultural knowledge and practice from the west. According to Andersson's findings, the Yangshao culture was preceded by the Qijia culture齐家 (2200–1600 BCE) that throve in today's Qinghai province, proposing an origin of the Yangshao pottery that was to be found even further in the west of China. Andersson's hypothesis sparked a heated argument about the origins of Chinese culture and civilization that dominated archaeological circles in China for decades. Andersson's diffusionist approach was fiercely contested by contemporary and later Chinese scholars, yet it played into the debate about single, dual or even multiple origins of Chinese civilization that reverberated in the nationalist outlook and scholarly

discussions of the discipline in later years (Liu 2017). Ultimately, Andersson's hypothesis was refuted by pioneering archaeologist Xia Nai's夏鼐 (1910–1985) excavations of Qijia culture remains in Qinghai province during the 1950s, proving that the Yangshao culture was in fact older than the Qijia culture. This, of course, disproved a western origin of the Yangshao culture, yielding a considerable increase in nationalist rhetoric in Chinese archaeological discourse of the day (Liu 2017).

The Longshan Culture

When the Longshan龙山 culture (ca. 3000–1900 BC) was first excavated at the Chengziya 城子崖site in Shandong by Wu Jinding吴金鼎 (1901–1948) in 1930, Chinese archaeologists were quick to ascertain the autochthonous nature of the found black pottery. For the first time material evidence confirming the existence of an ancient indigenous Chinese culture that flourished in the east of China was available for scientific study. The Yangshao and Longshan cultures were believed to have fused with each other – thus suggesting a dual origin of Chinese civilization – and eventually shaped what was later to become the Shang dynasty (Liu 2017; Bagley 1999).

A Reappraisal of the Past: The "Doubting Antiquity School"

During the formative years of Chinese archaeology, many of the long-established historical narratives were challenged by an ever-growing awareness of and appreciation for modern field methods and new approaches towards the reconstruction of China's past. In the search for scientific evidence, Confucian notions of history and historiography were re-examined and scrutinized. Chinese intellectuals and scholars of the period like Hu Shi 胡适 (1891–1962), Gu Jiegang 顾颉刚 (1893–1980), and Qian Xuantong 钱玄同 (1887–1939) began to waver in their convictions as to the consuetudinary tropes of the origins and evolution of Chinese civilization. The so-called "Doubting Antiquity School" (*Yigupai* 疑古派) questioned the authenticity of pre-Qin historical texts and the accuracy of the dynastic histories. They disputed the notion that the Grand Historian Sima Qian 司马迁 (145–86 BC) could have had access to reliable historical sources from antiquity detailing an ever distant past that otherwise has not left any surviving records. However, when archaeological excavations unearthed the inscribed Shang period oracle bones and tortoise shells in Anyang which detailed many aspects of the dynasty's history that were consistent with Sima Qian's *Records of the Grand Historian* (Shiji 史记) – thus substantiating its historic lore – the critical approach of the "Doubting Antiquity School" gradually became invalid (Hon 1996).

Chinese archaeologists of the time eagerly strove to prove the indigeneity of Chinese culture and to fend off suggestions of foreign origins as laid out in Andersson's diffusion hypothesis, engaging in the reconstruction of a national identity centered on cultural history and its material remains (Liu 2017). Despite the political fragmentation and rampant warlordism pointing to the inevitable fate of the Republic on mainland China during the years leading to the Japanese invasion in 1937, the young discipline of archaeology flourished and produced the first generation of native Chinese archaeologists such as Liang Siyong 梁思永 (1904–1954) and Xia Nai, who came to dominate the field for decades. As of 1937, the year of the outbreak of the second Sino-Japanese War, most excavations and archaeological surveys were suspended, except for some fieldwork in remote areas unaffected by the war. During the years of civil war (1945–1949), no major excavations were conducted. It was only after the founding of the People's Republic of China in 1949 that archaeological work resumed.

1949–1976

Chinese Archaeology in the Age of Marxism and Maoism

The decades leading from the founding of the People's Republic of China in 1949 to the death of Mao Zedong and the end of the Cultural Revolution in 1976 saw many developments in the field of Chinese archaeology: excavations, formerly concentrated on well-defined areas, were

conducted all over the country, providing new data and bridging some of the obvious lacunae earlier archaeological endeavors had left open; the systematic training of young archaeologists and the establishment of archaeological institutions and museums; the adoption of new dating and excavating methods; the publication of finds and data. However, the new ruling Communist Party also quickly recognized the potential archaeology had as an instrument of propaganda and so political ideology came to play a more substantial part in Chinese archaeology than ever before. While first efforts to align traditional historical Chinese narratives with Marxist interpretations of history can be found in a book by writer and politician Guo Moruo郭沫若 (1892–1978) called *A Study of Ancient Chinese Society* (中国古代社会研究 Zhongguo gudai shehui yanjiu) published in 1930, it was not until the early 1950s that Marxist evolutionary interpretations of human history and their Maoist extrapolations set the background against which Chinese archaeology developed its theoretical framework that was to dominate archaeological research for next three decades. Dialectical materialism on the one hand and class struggle on the other were the two guiding principles Chinese scholars of the day had to grapple with, although the historiographic leanings of Chinese archaeology never ceased to influence the discipline (Falkenhausen 1993; Chang 1981). Yet, despite ideological trench-fighting Chinese archaeology largely remained fixated on elites and the center of Chinese civilization instead of turning to the common people and the periphery. Many prominent archaeologists of the time like father of Chinese "socialist archaeology" Xia Nai, who became the first director of the newly founded Institute of Archaeology within the Chinese Academy of Sciences in 1950, adjusted to the new political and ideological challenges to the field. During his tenure, state-commissioned salvage excavations surged due to the enormous increase in construction projects that were undertaken everywhere in the country (Liu 2017). Interpreting Chinese history by using Marxist models came to shape Chinese archaeology and prehistoric research for the next 30 years. In addition to the quest of identifying the very roots of Chinese culture and civilization which had not been given up after the communists seized power, lending credence to the Marxist interpretations of Chinese history by virtue of archaeological finds was understood as the new mission of the field.

In 1950, archaeological work resumed at the sites of Anyang and Yangshao, both of which had been abandoned in 1937. Dating endeavors at the Yangshao site initially indicated that it had been among the earliest Neolithic cultures in China. Excavations at Miaodigou in Henan province unearthed a type of pottery that pointed to the existence of a transitional culture between the Yangshao and Longshan cultures, attesting to the fact that the two cultures were, indeed, successive instead of contemporaneous, indicating a single source Chinese civilization and culture originated from (Liu 2017; Chen 2009). Later excavations at the sites of the Hemudu culture 河姆渡 (5500–3300 BC, discovered in 1973) in Zhejiang province, the Peiligang culture 裴李岗(7000–5000 BC, discovered in 1977) in Henan or the Nanzhuangtou culture南庄头 (12.600–11.300 BC, discovered in 1986) in Hebei province, however, proved to be much older than the remains both at Yangshao and Longshan, signifying a more varied origin of Chinese civilization than previously assumed (e.g. cf. Guo et al. 2002). Anyang on the other hand was discarded as the earliest capital of the Three Dynasties period after older remains of city, palace, and burial structures were excavated in Erligang二里冈 and Erlitou 二里头, Henan Province, inciting passionate debates about the historicity of the much contested Xia dynasty (Liu 2009; Zhao 1987).

Archaeology During the Cultural Revolution

Much like today, archaeological finds during the 1950s and 1960s were regarded as material evidence of a highly developed Chinese culture that was to reinstate national pride in the Chinese people, at the same time functioning as a means for mass education and the development of class-consciousness (Liu 2017). The objects retrieved from archaeological excavations were not only seen as proof and examples of the highly

developed productivity and creativity of early levels of Chinese civilization but also as material evidence of a bygone past that allowed for the people to be exploited and enslaved by the feudal ruling class. When the Cultural Revolution started in 1966, most archaeological work ceased, although never completely. Some projects, including salvage excavations, were still conducted and publicized as achievements of the "Great Proletarian Cultural Revolution guided by Chairman Mao's revolutionary line and supported by the broad worker, soldier, and peasant masses" (Xia 1974), e.g., excavations of Shang period burial structures in Changsha, Hunan province, in 1966; the discovery of the jade burial suits of Prince Liu Sheng刘胜 (died 113 BC) and his consort dating from the Western Han dynasty (220 BC -9) in their tomb in Mancheng, Hebei province, in 1968; or assemblages of fine pottery from the Tang dynasty (618–907) found in tombs in Luoyang, Henan province, in 1971 (Xia 1974). Despite these efforts, the Cultural Revolution and its social, political, ideological, and economic bearing greatly impacted contemporary archaeology and archaeologists. Scholars and university professors were demoted, students joined the Red Guards and resorted to criticizing and ousting their former teachers, and a whole generation of archaeologists, students and professors alike, was relocated to the countryside to learn from workers and peasant-farmers. Even though the Red Guards were dismissed by Mao Zedong in 1969 and the first international exhibitions of Chinese archaeological finds were held in London and Paris in 1973 to showcase China's past glory and her modern day scholarly and technological accomplishments, it was only after Mao's death in 1976 and the demise of the Gang of Four that Chinese archaeology, like all Chinese scholarship, gradually recovered.

1978–1997

Reform and Opening-Up

With the discovery of the Terracotta Army (Bingmayong 兵马俑), in the vicinity of the First Emperor's (Qin Shi Huangdi 秦始皇帝, 259/221–210 BC) tomb northeast of Xi'an in Shaanxi Province in 1974, Chinese archaeology entered a new phase. Due to the political and social unrest of the years towards the end of the Cultural Revolution, the discovery of the pits containing over 10,000 figurines of warriors, horses, and carriages was disclosed to the public with a delay of more than a year in July 1975. The Terracotta Army soon became world famous and archaeologists and visitors alike flocked to the site. In 1979 a museum was built to cater for the rising numbers of tourists and to educate the Chinese public about what was considered one of the most important archaeological finds of the century, equaling the discovery of the tomb of Pharaoh Tutankhamun in the Valley of the Kings by Howard Carter in 1922. For the first time, an archaeological site in China became the centre of attention of international media coverage and the first international exhibition of the terracotta warriors was curated in Melbourne in 1982 (Portal 2007). Further attesting to the new open door policy that was implemented during the reform era under Deng Xiaoping邓小平 (1904/1978–1997), the Terracotta Army and the Mausoleum of the First Emperor were among the first Chinese sites ever to be included in the UNESCO World Heritage list in 1987, marking an initial step towards the globalization of Chinese archaeology. While during the Cultural Revolution most of China's state-to-state foreign relations remained tense and complicated – despite China's accession to the United Nations in 1971 – the 1980s, however, witnessed a considerable increase in diplomatic and scholarly exchange between China and the rest of the world. Among his "Four Modernizations" (si ge xiandaihua 四个现代化) as part of his reform policies that were to transform China into a modern and competitive nation and to rejuvenate her economy, Deng Xiaoping stressed the role of scholarly exchange, science, and technology as one of the four major fields in which China needed to catch up with modern times (the others were agriculture, industry, and national defense). Contrary to what has been long-established ideology, Deng Xiaoping declared the end of the class struggle, and an overall modernization of all parts of China's socio-economic, educational, and

scientific/scholarly structures became the new future directive (Hsü 1990). Because of the opening and reform policies and due to growing scholarly exchange, Western state-of-the-art archaeological methods and theories were introduced to China. And while Deng Xiaoping was calling for a new market economy and rapid social change, Chinese archaeology of the day was to reach a subtle balance between the problem of defining a "modern archaeology with Chinese characteristics" and a growing nationalism that was in part rooted in the new challenges China faced in her relationships with other countries in the globalized world (Liu 2017). Apart from ongoing and ever-expanding excavation efforts throughout the country, the 1980s and 1990s witnessed a significant shift in archaeological debates about the origins of Chinese civilization. While during the first decades of the People's Republic of China a center-periphery theory with a focus on the cultural predominance of the Han majority was in place, archaeologists in the early 1980s shifted their interests to reflect the changed political climate after the Cultural Revolution: renowned archaeologist Su Bingqi苏秉琦 (1909–1997) proposed an approach called "regional systems and local cultural series" (quxi leixing 区系类型) which stressed a multiregional origin of prehistoric Chinese civilization, mostly based on finds of ceramic assemblages that suggested the independent development of different regional cultures (Su 1984). Su's approach supplied the contemporary academic debate with a frame of reference for the reconstruction of Chinese national history that accounted for the shifting approach towards the question of multiregional origins of Chinese civilization (Falkenhausen 1995), at the same time reflecting the changing political climate that also addressed the multiethnic realities of modern China (Heberer 2017). Another important development of the decade was the increased commitment of the People's Republic of China to multilateral and international cooperation. Not only did China enforce a domestic law for the protection of cultural relics and against illicit trade and smuggling in 1982, she also acceded to the major international convention for the protection of cultural heritage, the UNESCO Convention of 1972, which China ratified in 1985, having an immediate impact on the archaeological discourse of the time: in 1991, China officially allowed for international collaborations and foreign archaeologists from the US, Great Britain, France, Germany, Israel, Korea, etc. to work in the country for the first time in over 45 years (Liu 2017). Despite a decidedly nationalist stance of most of the academic discourse in Chinese archaeology at the time, scholarly exchange, international conferences, and joint fieldwork, as well as the growing influx and reception of international scholarly publications changed the academic environment to a more collaborative and co-operative one.

The Xia-Shang-Zhou Chronology Project

Despite these developments, the mid 1990s witnessed a noticeable resurgence of nationalism in China that was in part a reaction to the social changes and challenges brought about by Deng Xiaoping's economic reform but also in part to the lack of a new, legitimizing ideology that filled the conceptual void after the end of Maoism (Gries 2004). These conditions prepared the ground for an academic opposition against what was perceived as foreign interference and criticism of the credibility and reliability of Chinese archaeological dating methods: the Three Dynasties Chronology Project (Xia Shang Zhou duandai gongcheng 夏商周断代工程). This large-scale project was geared towards the identification and documentation of the primal stages of dynastic rule in China and was included in the government's ninth 5-year-plan of 1996 (1996–2000) and launched the same year (Shaughnessy 2009). The project originated in the attempt to adjust China's history and its prehistoric beginnings to the histories of ancient Egypt and Mesopotamia, trying to bridge the existing gap of 1000 years between them. The project started after a state visit of a Chinese diplomatic delegation to Egypt where the delegates were introduced to a newly developed dating scheme, which combined radiocarbon dating with historical textual analysis and other methods, for the reign periods of Egyptian Pharaohs, providing scholars with a detailed chronological record of dynastic rule in

ancient Egypt. China, they felt, was lacking in that respect, not only with regard to the time span Chinese archaeological surveys recorded but also with regard to their accuracy. The main objectives of the project were (1) to set up a detailed timeline for the early period of dynastic rule in China from the beginnings of the Shang dynasty to the beginnings of the Zhou dynasty; (2) to determine a chronology for the Western Zhou period; (3) to draft a basic time frame for the Xia dynasty (Xia-Shang-Zhou Duandai Gongcheng Zhuanjiazu 2000). After 4 years of research that involved more than 200 scholars from a multitude of scientific backgrounds, the project had yielded none of the projected results, instead it created controversial debates about its objectives, its methods, and its results – or the lack thereof (Shaughnessy 2009). Yet, a great many projects followed the Xia-Shang-Zhou Chronology Project under the new Searching for the Origins of Chinese Civilization Research Scheme (中华文明探源工程 Zhonghua wenming tanyuan gongcheng, 2002–2015) set up by the Ministry of Science and Technology (中华人民共和国科学技术部 Zhonghua renmin gongheguo kexue jishu bu), albeit smaller in scope, but nevertheless as ambitious as the Chronology Project in their quest to identify the earliest traces of Chinese civilization (Wang 2011). Studying the origins of China's earliest cultures, the Research Scheme also aimed at tracing cultural flows and interactions between ancient China and its neighbors in order to understand China's role in the development of world civilizations (Lee 2002).

Key Issues/Current Debates

Chinese Archaeology in the New Millennium

While China witnessed rapid social change and economic development since Deng Xiaoping's new policies of "reform and opening-up," leading towards a package of economic reforms termed "Socialism with Chinese characteristics," the political objectives of Chinese archaeology have changed only slightly. During the Cultural Revolution and the years of Mao's rule archaeology served as a means for displaying the achievements and the resilience of the people as well as exposing the failures and hardships of the past, caused by an unjust socioeconomic and political system that was to be swept away by the socialist revolution of the communist party and its leaders. Today archaeological finds serve as a means to, again, reinstate national pride and dignity in the Chinese people and to cater for a collective cultural elation that is supposed to make up for the lack of political freedom in China's One-Party-State. Since President Xi Jinping习近平 (∗1953) took office in 2013, China has witnessed a surge in nationalism and communist party propaganda rhetoric reminiscent of the past. Much like their predecessors in the 1990s and early 2000s, the current Chinese government views archaeology not only as a tool for mass education but also as an important asset in its foreign- and geopolitical strategy (Perry 2017).

"One Belt One Road"

The "One Belt One Road" initiative (Yi dai yi lu 一带一路), first launched in 2013 at the direction of President Xi Jinping, plays a significant role in China's current development strategy as it is the country's largest investment and infrastructure project to date. Both the "Economic Belt Silk Route" (Sichou zhi lu jingji dai 丝绸之路经济带) and the "21st Century Maritime Silk Route" (Ershiyi shiji haishang sichou zhi lu 二十一世纪海上丝绸之路), following historical trade routes along the silk road that connected China with Central Asia, Persia, India, and the Middle East from the times of the Han dynasty to the decline of the Mongolian Empire, are not only of paramount economic and political importance to the Chinese state with regard to the development of a unified global market that involves the economies of more than 60 countries spanning four continents, but also with regard to China's cultural and – therefore – archaeological agenda (Sidaway and Woon 2017; Aoyama 2016). This includes joint archaeological projects and scholarly co-operations with countries and institutions along the Overland Silk Road – e.g., in Tajikistan and Uzbekistan, but also with more remote partners at the other

end of the Eurasian continent like the collaboration between the Palace Museum in Beijing and the Department of Archaeology at Durham University (Durham University 2016) – as well as along the Maritime Silk Road in South East Asia. This development points to a shift in China's national cultural and archaeological discourse and its conceptual specifications as archaeological research in China today is closely linked to the country's geopolitical and economic agenda (Liu 2017).

Underwater Archaeology

Although comparatively small in budget and scope, China also riveted on her underwater cultural heritage and invested in the development of an autochthonous underwater archaeology since the late 1990s, which, alongside her military presence in the South China Sea, emphasizes her claim to territorial and economic hegemony in the area (Hoagland 1997). Initially China started her underwater archaeology program as a counter measure against treasure hunters illicitly salvaging objects from Chinese ships sunk in international waters. However, China's determination to become a factor in marine archaeology follows yet another agenda: firstly, Chinese shipwrecks found in the South China Sea as well as other maritime regions of East- and South-East Asia conform seamlessly with the narrative of China's geopolitical identity as an assurgent international trading nation that boasts a long tradition of trade and commerce dating back at least to the Ming dynasty. Secondly, the discovery of shipwrecks and other finds in the South China Sea is regarded as proof of China's inherent right to her claims to territorial hegemony over her neighbors in the ongoing quarrels about maritime boundaries and exploitation rights. Archaeological evidence of a century-long Chinese presence in the region therefore equates to China's claim to these waters as traditionally being part of the Chinese territory. Irrespective of ongoing academic debates, offshore exploration and the drilling of crude oil as well as military operations and maneuvers make the South China Sea an area of core interest for the People's Republic of China. Thus not only underwater archaeology but archaeology as a whole serves a meaningful purpose in the country's current – and future – political and strategic agenda (Adams 2013).

Future Directions

In his book on archaeological evidence of the origins of the Chinese people, Su Bingqi declared that "a golden age of Chinese archaeology is arriving" (Su 1994). Looking back at his statement today, he was certainly right. Over the course of the last century, tens of thousands of archaeological sites and millions of objects dating from the Palaeolithic to the beginning of the Qing dynasty have been found in Chinese soil, and a vast quantity of to date undiscovered sites is expected to be excavated in the near future. These finds not only attest to the cultural achievements of China but at the same time to her political power and significance, defining her place among the oldest human civilizations in the world, as well as to the future potential of archaeology as one of the "most rapidly developing fields of social science in China" (Liu 2017). Yet, due to the growing decentralization that diverted cultural authority from the central government in Beijing to the provincial governments over the last decades, leaving them responsible for museums, public administration of cultural heritage, and archaeological excavations, the country's provinces witness striking disparities in funding and infrastructural assistance of archaeological projects (Zan 2014). With regard to the allocation of funds and resources for archaeological projects, the rich provinces of the east coast have a clear advantage to their poorer neighbors in central or western China, leading to a geographical imbalance and a divide between the east and the rest of the country that will probably grow even further (Visconti 2016). Moreover, Chinese archaeology today is not only faced with financial and infrastructural concerns as well as with methodological questions and the issue of the general reliability of data from Chinese excavations but also with a certain reluctance to adopt a more global perspective within Chinese academic circles. Yet, international co-operations are rapidly growing in

number and will likely continue to do so, as will international joint scholarly publications and translations of publications from western archaeological journals into Chinese and vice versa (Visconti 2016). However, and notwithstanding the breath-taking pace of change in present-day China, it does not seem feasible that the country will give up its nationalist and ideology-ridden approach towards archaeology and the (re-) construction of a history that serves the present in the foreseeable future.

Native American Graves Protection and Repatriation Act (NAGPRA), USA

D. Rae Gould
University of Massachusetts Amherst, Amherst, MS, USA

Brief Definition of the Topic

The Native American Graves Protection and Repatriation Act (NAGPRA) (sections 3001 through 3015 of volume 25 of the United States Code) is a federal law instituted in 1990 to facilitate the return of human remains, funerary objects, sacred objects, and objects of cultural patrimony to lineal descendants, Indian tribes, and Native Hawaiian organizations. The law provides a process for the return of certain items and ancestral remains held by federal agencies, museums, and educational institutions obtained through archaeological excavations or other collection practices to these groups, which are broadly defined to be Native American. NAGPRA also recognizes the interest of Native American tribes affiliated with burial sites discovered on federal and tribal lands through present-day activities.

Human remains must be clearly identified as "Native American" to be repatriated by a tribe. Funerary objects that fall under NAGPRA fall into two categories: associated funerary objects and unassociated funerary objects. Associated funerary objects are documented to a specific burial site and/or associated with human remains

that are in the possession of an agency, museum, or institution. The funerary objects and human remains, however, do not necessarily have to be at the same location, just known to have once been together in their original context. Often funerary objects and human remains were separated once excavated and are today located in separate agencies, museums, or institutions. Unassociated funerary objects are either known or believed to have been from a burial context, but the human remains once associated with them are now not in the possession of a known agency, museum, or institution. This often occurs when human remains become undocumented or lost by institutions that once held them but documentation on the funerary objects is clear.

Sacred items that can be repatriated through NAGPRA include specific ceremonial objects used by Native American religious leaders for religious practices, and that are still needed for present-day practices.

These may include items such as pipes, baskets, clothing, masks, or other religious items used in ceremonial practices. Objects of cultural patrimony are defined as "having ongoing historical, traditional, or cultural importance central to the Native American group or culture itself, rather than property owned by an individual Native American" (National NAGPRA n.d.). These objects should never have been separated from the group. The famous wampum belts of the Haudenosaunee (or Iroquois) that represent an important part of tribal history are one example of this type of object.

All federal agencies are required to comply with NAGPRA, as well as any public and private museum, educational or other institution that has received federal funds. The Smithsonian Institution must comply with a separate repatriation law, enacted in 1989, entitled the National Museum of the American Indian Act. Compliance involves providing an inventory of Native American humans remains (whether culturally affiliated or not yet culturally affiliated) and consulting with tribes to determine cultural affiliation, as well as sending summaries of artifact collections with Native American objects to tribes that may have an interest in these collections. Cultural affiliation is defined as "a relationship of shared group identity which can be reasonably traced historically or prehistorically between a present day Indian tribe or Native Hawaiian organization and an identifiable earlier group" (National NAGPRA). In 2010, an amendment to the Act provided a process for the return of human remains and objects that have been defined by institutions and museums as "culturally unidentifiable" or "CUI" (see http://www.gpo.gov/fdsys/pkg/FR-2010-03-15/html/2010-5283.htm for more information).

NAGPRA only applies to tribes as defined by the US federal government, that is, federally acknowledged tribes and Native Hawaiian organizations with a government-to-government relationship with the US government. Non-federally recognized tribes, or lineal descendants from such groups, may not directly make claims through NAGPRA, although they may request repatriations through the National NAGPRA Review Committee, which meets twice per year to hear such requests, disputes between institutions and tribes, and conduct other business related to the law.

Many consider NAGPRA to be a cultural property law, while others consider it more of a human rights law that was the result of decades of protest and activism by Native American leaders. The several decades leading up to the passing of the Act in 1990, in particular, saw a number of high-profile protests focused on the public display in museums and institutions and continued excavation of Native American burials and objects across the country. While the law has facilitated a large number of repatriations over the past several decades, many thousand human remains and objects still await repatriation and lack of compliance by agencies, museums, and institutions has been an ongoing issue.

Natural Hazards Versus Cultural Heritage

Ionut Cristi Nicu
Norwegian Institute for Cultural Heritage Research (NIKU), High North Department, Fram Centre, Tromsø, Norway
Flinders University, College of Humanities, Arts and Social Sciences, Adelaide, SA, Australia

Introduction

Natural hazards are usually approached by geosciences (geology, geography); they are a cause of planetary evolution that can be divided into geological hazards (earthquakes, volcanic eruption), meteorological hazards (hailstorm, heat wave, cyclones, ice storm, tornado), and hydrological hazards (floods, droughts, mudslides). Over the last decades, due to the technological evolution, the research undertaken in order to understand and predict natural hazards has made serious progress. When a natural hazard is affecting the cultural heritage integrity, the process can be fast and lead to permanent destruction or slow, depending on the severity of the hazard. Along history, natural hazards lead to the destruction of some famous monuments: the pyroclastic flows from Vesuvius completely destroyed Pompeii in 79 A.D.; the Colossus of Rhodes and the Pharos Lighthouse have been destroyed by earthquakes in 227 B.C. and in the fourteenth century, respectively; mausoleum of Halicarnassus has been destroyed by floods and earthquakes in the fifteenth century; (Will and Meier 2007), etc. The consequences are disastrous and important data is lost; this information could offer more insights into human evolution (Romanescu 2013a, b), the habits of a certain population, people's behavior, or evolution of culture.

N

Definition

Natural hazards are severe and extreme weather and climate events that occur naturally in all the parts of the world; some areas of the globe are more vulnerable to certain hazards than others, according to the local natural characteristics. The global climatic changes have a significant role in the triggering and development of natural hazards, which are exponentially increasing every year (Will and Meier 2007). The term cultural heritage was known since antiquity (Migoñ 2013) and represents an expression of the way in which a community developed and lived, passed on to future generations, including customs, practices, objects, places, values, and artistic expressions. Since humans were using the environment in order to live and search for food, they inevitably got in contact with natural hazards, whether they were aware or not. The

importance and value of cultural heritage are growing every year and are reflecting the scientific, historical, economic (Romanescu 2014), and the artistic significance of an asset that has been created in the past and are part of the local community.

Historical Background

There are many studies that are applied for hazard identification, monitoring, analysis, and prediction, but not so many are applied in the field of cultural heritage. The beginnings of these studies are in the early 1970s, but in the recent years, the trend is growing; even so, the need of studies that treat both natural hazards and cultural heritage is tremendous (Agapiou and Lysandrou 2015). With the technological evolution and a continuously improved methodology, the number of studies is growing each year. Some of the hazards are easier to be identified, analyzed, and predicted. The most representative studies are related to gully erosion (Pederson et al. 2006; Romanescu et al. 2012a; Romanescu and Nicu 2014; Nicu 2016a; Nicu and Romanescu 2016) (Fig. 1), landslides (Sdao and Simeone 2007; Tarragüel et al. 2012; Sdao et al. 2013; Nicu 2017a; Nicu and Asăndulesei 2018) (Fig. 2), coastal erosion (Gontz et al. 2011; Khakzad et al. 2015; May 2015; Usmanov et al. 2018) (Fig. 3), and floods (Lanza 2003; Wang 2015). The continent with the highest number of studies is Europe, which also has the richest and most diverse cultural heritage in the world. The monuments that have a significant historical importance and an outstanding universal value are included in the UNESCO World Heritage List (WHL), which totalizes 1052 properties; they are divided into three categories: cultural sites, natural sites, and mixed sites (http://whc.unesco.org/en/list/). According to a UNESCO survey, 89% of all biosphere reserves, 82% of all geoparks, and 96% of World Heritage sites are exposed to at least one type of natural hazard, which can turn into a disaster and eventually affect the site's integrity. This means more than 1500 cultural and natural sites in 144 countries.

Key Issues/Current Debates

The world's cultural heritage is at great vulnerability (Nicu 2017b), as shown by a few studies that successfully integrated modern techniques (Agapiou et al. 2015) and historical maps (Nicu 2016b, 2017c) approaches. It is not only a scientist task to undertake research and to record the fact that cultural heritage is under threat from natural hazards, policy makers and local authorities need also to be involved. Saving as much spatial data as possible, integrating it with the help of GIS, generating 3D models (Romanescu et al. 2012b), and realizing soil erosion predictive models will lead to a better understanding for local authorities and stakeholders to plan economic activities, minimize damages costs, improve environmental protection, and the most important thing, and protect cultural heritage. The main issues that are leading to a bad management of cultural heritage are the lack of qualified personnel, the lack of funding, the lack of education of the community, and the lack of a complete inventory with a precise location. Conservation and protection strategies need to be implemented, according to the natural conditions of the affected areas; they have to be in accordance to the respective country/region legislation regarding the protection of cultural heritage and suppose to involve the local population, improvement in the administration of cultural heritage, development of cultural resources, and a sustainable use of cultural heritage resources.

International Perspectives

Risk assessment and reduction are one of the main challenges of the modern times, which nonetheless represent one of the main points on UNESCO's agenda. During the last years, at an international level, there have been a few research projects dealing with the use of modern technologies (RS and GIS) in order to evaluate, assess, manage, and predict natural and/or man-made hazards applied to cultural heritage. The projects can be considered as a base for future research and a good platform to unite researchers and

Natural Hazards Versus Cultural Heritage, Fig. 1 (continued)

N

authorities in the attempt to save the world's cultural heritage. A few of them are listed below:

1. Climate for culture (https://www.climateforculture.eu/index.php?inhalt=home) – the project was financed by the European Commission from 2009 to 2014; the main scope of the project was to employ simulation and modeling tools to better predict the influence of the changing outdoor climate on the microclimate in historic buildings until 2100 and to assess the damage potential of these microclimates on art collections in different climate areas. Buildings from different climate areas and with an outstanding universal and cultural value were used as case studies; the latest technology developed within the framework of important European projects was employed. The project leader was the Fraunhofer-Gesellschaft research organization from Germany, along with research institutes and universities from Europe (Czech Technical University of Prague; Italian National Research Council; University of Zagreb; Foundation for Research and Technology, Greece; Max Planck Institute for Meteorology; Technical University Munich; Eindhoven University of Technology; University of Ljubljana; Gradbeni Institut ZRMK, Slovenia; Uppsala University; National Trust for England, Wales and Northern Ireland; Center for Documentation of Cultural and Natural Heritage, Egypt; the National Institute of Cultural Heritage, France; the Evangelical church, Romania; etc.). The results consisted of a number of 30 publications and 22 presentations, which brought significant updates and new insights into conservation and preservation of cultural heritage.
2. Fluvial processes and sediment dynamics of slope channel systems: Impacts of socioeconomic and climate change on river system characteristics and related services (FLUMEN) (http://flumen-irses.eu/) – it was a joint project that ran in 2012–2016 between University of Florence (Italy), Moscow State University (Russia), Kazan Federal University (Russia), University of Palermo (Italy), University of Tübingen (Germany), Kazimierza University (Poland), Stockholm University (Sweden), Alexandru Ioan Cuza University of Iasi (Romania), and Institute of Ecology and Geography (Republic of Moldova); the project studied the effects of changes on river systems at different spatial and temporal scales and assess the impact on cultural heritage sites, among other issues. The special focus was on remote sensing, aerial photography, field surveys with total station and GPS, and statistical analysis, all integrated into a GIS.
3. Archaeological analysis and heritage valorization of three landscapes of the Roman conquest of Hispania (second to first centuries B.C.). Sub-project: Southwest of Hispania Ulterior (Spain) (http://oliba.uoc.edu/UAB/) – the project is a joint initiative of three research centers, Autonomous University of Barcelona, University of Alicante, and CSIC Institute of Archaeology-Mérida; the final aim of the project is to help transfer to society the results of several years of survey and excavation of the research team in three different regions of former Hispania. The results will offer a high potential in what regards the cultural and touristic development of rural areas, with the revalorization of the rich archaeological heritage that can become a valuable resource for local development. The methodology is based on geospatial technologies, remote sensing, aerial archaeology, pedestrian, and geophysical survey.

Natural Hazards Versus Cultural Heritage, Fig. 1 Gully erosion affecting two archaeological sites (*Mlada* and *Dealul Manastirii*, located in the northeastern part of Romania, Valea Oii catchment; Cucuteni-Baiceni gully); (**a**) the dislocated area on 10.10.2012; (**b**) the dislocated area on 10.05.2013; (**c**) thalweg after the junction of both torrents before the thresholds being built; (**d**–**f**) concrete thresholds as part of the mitigation measures to stop the erosion process built in the summer of 2014; (**g**) black locust saplings planted in the upper part of the gully; (**h**) fences of fascine from the right side of the gully; (**i**) topographic surveys of the gully on 11.09.2014

Natural Hazards Versus Cultural Heritage, Fig. 2 (continued)

N

4. Insurance as a tool to protect cultural heritage against natural and man-made hazards – a joint project between the Institute of Archaeological Heritage, Monuments and Sites IBAM, Italian National Research Council, and the Department of Economic Science, University of Salento (Italy), which aims to investigate the role of the insurance in the protection of cultural heritage against natural and man-made hazards.
5. Remote sensing science center for cultural heritage (acronym ATHENA) (Cyprus) (https://athena2020.eu/) – this project aims to establish a Center of Excellence in the field of Remote Sensing for Cultural Heritage in the areas of Archaeology and Cultural Heritage through the development of an enhanced knowledge base and innovative methods; the center represents a joint project of the Remote Sensing and Geo-environment Research Laboratory at the Cyprus University of Technology (CUT), the Institute of Archaeological and Architectural Heritage of the National Research Council of Italy (IBAM-CNR), and the German Aerospace Center (DLR). The project is according to the EU policies and international conventions related to cultural heritage protection, management, and good practice guides.
6. Cultural landscape risk identification management and assessment (acronym CLIMA) (Cyprus) – the project aims to promote interdisciplinary research, based on a soil-oriented approach, to develop effective tools for the authorities responsible for cultural landscape preservation; also, the project is to design and implement a Web GIS-based multitask platform in order to integrate different remote sensing techniques. They will be used to map, diagnose, and monitoring the cultural landscapes including buried and exposed archaeological remains.
7. Nondestructive approaches to complex archaeological sites. An integrated applied research model for cultural heritage management (acronym PROSPECT) (http://arheoinvest.uaic.ro/research/prospect/) – the project is a joint initiative of Alexandru Ioan Cuza University of Iasi (Interdisciplinary Research Department – Field Science, Arheoinvest Platform), Romanian Academy (Iasi Institute of Archaeology), and SC Arheo Management SRL; it is funded by the Romanian National Research Council (grant no. 314/2014). The main objective of the project is the elaboration and implementation of a functional applied research model based on integration and development of noninvasive techniques, with the goal of understanding and evaluating the complexity of the prehistoric archaeological sites. The specific objectives refer to identifying habitation models, describing the prehistoric communities' behavior in certain environmental conditions, evaluating and monitoring the natural hazards that affect the prehistoric sites, and proposing a touristic management model.
8. Research laboratory "Kosmoecology" as a part of a strategic academic unit "Astrochallenge: cosmology, monitoring, navigation, applications" (acronym OPENLAB) – the project is a joint between Alexandru Ioan Cuza University of Iasi (Interdisciplinary Research Department – Field Science, Arheoinvest Platform, Romania) and Kazan Federal University (Russian Federation). The project aims to test different GIS and RS techniques applied to cultural heritage assessment and preservation in Romania and Russian Federation; the focus is on

Natural Hazards Versus Cultural Heritage, Fig. 2 Landslide susceptibility map (*Dealul Mare Filiasi/Dealul Boghiu* archaeological site – Chalcolithic/Cucuteni A_3, located in the northeastern part of Romania, Valea Oii catchment) overlaid by the main natural and anthropic factors; (**a**) the northern extremity of the landslide depletion area; (**b**) sheepfold located in the northwestern part of the site on the landslide body; (**c**) the escarpment area measuring about 6 m; (**d**) gully erosion located at the base of the landslide body; (**e**) archaeological remains (Chalcolithic pottery pieces) carried down the landslide body; (**f**) scattered pottery remains inside the settlement

Natural Hazards Versus Cultural Heritage, Fig. 3 Coastal erosion of archaeological sites ((**a**) case of *Devichy Gorodok hillfort* – Bulgarian Culture X-XIII centuries, located in the Republic of Tatarstan, Spaskiy municipal district, on the left bank of Kuibyshev Reservoir, Russian Federation); (**b**) topographic surveys overlapping the Soviet aerial image from 1958, highlighting the fast coastal recession; (**c**, **d**) dislocated material during the July 2014 field trip; (**e**) animal remains coming to surface as a consequence of coastal erosion in the eastern part of the site; (**f**, **g**) dislocated areas during the December 2015 field trip; (**h**) 3D modeling of the settlement (hillfort) before being completely destroyed

monitoring cultural heritage sites located in coastal areas of Russia's reservoirs and to test landslide susceptibility models in the assessment of cultural heritage sites from the Moldavian Plateau, Romania.

9. Protection of European cultural heritage from geo-hazards (acronym PROTHEGO) (http://www.prothego.eu/home.html) – a joint research project funded between 2015 and 2018, under the framework of the Joint Programming Initiative on Cultural Heritage and Global Change (JPICH), Heritage Plus, under ERA-NET plus and the Seventh Framework Programme (FP7) of the European Commission. The project partners are the Institute for Environmental Protection and Research (ISPRA, Italy), Natural Environment Research Council (NERC, UK), Cyprus University of Technology (CUT, Cyprus), University of Milano-Bicocca (UNIMIB, Italy), and Geological Survey of Spain (IGME). The main goals of the project are to enhance cultural heritage management practices at national level; reinforce institutional support and governance through knowledge and innovation; identify, assess, and monitor risks; and strengthen disaster preparedness at heritage properties in the future.
10. Multidisciplinary complex project for the monitoring, conservation, protection, and promotion of the Romanian cultural heritage (acronym RO-CHER) – the project is

N

Natural Hazards Versus Cultural Heritage, Fig. 4 Technical details of the concrete thresholds built inside the Cucuteni-Baiceni gully (Valea Oii catchment, NE Romania) in order to stop the gully head retreat

financed by the Executive Agency for Higher Education, Research, Development, and Innovation Funding (UEFISCDI), Romania, from 2018 to 2020. The main coordinator of the project is the Romanian Space Agency, together with the National Institute for Research and Development in Chemistry and Petrochemistry (Bucharest), University of Agronomic Sciences and Veterinary Medicine of Bucharest, National Museum of the Union (Alba Iulia), and Museum of Dacian and Roman Civilisation (Deva). The project has four main objectives: monitoring the cultural heritage objectives with the aid of space technologies, development of materials and innovative techniques based on soft nanomaterials for safeguarding the cultural heritage, recommendation of an integrated management system (conservation, restoration, protection) for mobile and immobile cultural heritage objectives, and promoting cultural heritage by using state-of-the-art technologies of digital reconstruction.

The above projects brought significant insights into using modern technologies in the field of cultural heritage and their contribution is highly acknowledged. More projects like these are needed in order to save as much spatial data as possible in order to mitigate the negative effects of natural hazards on cultural heritage.

Future Directions

The application of soil erosion (gully erosion, landslides – Fig. 2) predictive models to cultural heritage assessment would be a proper way of mitigation (Nicu 2018). Once the assessment and mitigation are done, the proposals for prevention (Fig. 4) and preservation can start. Special attention must be given to areas with high and very

Natural Hazards Versus Cultural Heritage, Fig. 5 Instability process of the decorated roof at *Temple of Bacchus*, part of Baalbek Roman Archaeological Site (the largest and most impressive Roman Temple complex in the world, part of UNESCO World Heritage, Beqaa Valley, northeastern Lebanon)

high erosion potential. Other processes that should benefit from researchers attention are weathering and biotic processes (root wedging); weathering represents a natural process that affects cultural heritage stability over long periods of time (Fig. 5). The prevention and protection of cultural heritage from natural hazards is a difficult issue, due to their location in areas prone to these hazards. For example, the steep slopes used in the past by Neolithic population as a defensive system became in time areas with a very high erosion potential; moreover, these areas represent landslide depletion areas or gully lateral banks. Sites located near coastal or seismic prone areas are the most vulnerable; in this case, prevention measures should be taken, like consolidation.

The significance of cultural heritage and the opportunities that this part of the sector could create for both professionals in the field and for local communities is of great value; under a proper management and touristic promotion, it can boost the local economy and contribute to the population well-being. In order for this to be possible, preservation and mitigation measures need to be taken. Future mitigation measures can include restoration, excavation, site mapping, and eco-friendly erosion control measures. The measures undertaken have to be made in a sustainable way (Khalil et al. 2018). However, the research must be converted into policy action. There is a difficult issue in the attempt to financially evaluate the damages caused by natural hazards on cultural heritage; most of the monuments, not only those listed on the UNESCO WHL, have an outstanding universal value which goes beyond the material loss. It is a value that grows in time and gives the place a special and unique universal characteristic that cannot be found somewhere else.

Ndoro, Webber

Ancila Nhamo
History Department, University of Zimbabwe, Harare, Zimbabwe

Basic Biographical Information

Webber was born in Goromonzi, Zimbabwe, in 1959. He grew up in the Domboshava area just outside of Harare, the capital city of Zimbabwe. He did his Bachelor of Arts degree at the University of Zimbabwe from 1980 to 1982. He obtained an MPhil in archaeology at the University of Cambridge (1987) and MA in architectural conservation from the University of York (1990) and received his Ph.D. in Archaeology from the University of Uppsala (2000). Webber got into archaeology and heritage management by chance. It was during his undergraduate time that he was introduced to archaeology as part of the history courses. At the time, archaeology was not yet taught as a separate subject at the University of Zimbabwe. It was introduced in 1985. He, however, started practicing archaeology in 1985 after he moved to joined the National Museums and Monuments of Zimbabwe (NMMZ) as a curator. His initial responsibility was to look after archaeological collections in the Museum of Human Sciences in Harare (formerly Queen Victoria Museum) and to conduct archaeological field research within NMMZ's northern region. In 1987, he became the resident archaeologist at Great Zimbabwe, after its listing as a UNESCO World Heritage Site in 1986. In 1991, he was appointed national monument program coordinator. Ndoro left NMMZ to join the University of Zimbabwe as a lecturer in the Archaeology Unit in May 1994. He taught archaeology and cultural heritage management (CRM) course to both undergraduates and postgraduates. He worked for the university for 12 years during which time he had become a senior lecturer in the Department of History. Webber Ndoro joined ICCROM in 2002 as a project manager for AFRICA 2009. Although he had done a few assignments as a consultant and facilitator, this post exposed him to greater variety of issues within African heritage management. AFRICA 2009 was a successful Pan-African program geared toward finding lasting solutions to the management and conservation of immovable cultural properties on the continent. While archaeological in nature, many of these have historical and spiritual connections to living communities. This brings a management complexity which is not often encountered on other continents. In 2008, Webber Ndoro joined the newly established African World Heritage Fund (AWHF) as its inaugural director. This organization coordinates the effective management of World Heritage Sites on the continent. It also strives to increase the visibility of African World Heritage places by, among other things, helping African countries navigate the process of nominating their places of cultural and natural significance onto the World Heritage List. With AWHF, Webber (Fig. 1) has found an outlet for the issues that he had championed for many years. Under his stewardship, AWHF has assisted in the inscription of close to 20 sites from various African countries onto the World Heritage List. Several more are on the tentative list.

Major Accomplishments

Webber Ndoro was probably the first professionally trained Zimbabwean heritage manager.

Ndoro, Webber, Fig. 1 Webber Ndoro standing in the parallel passage of the Great Enclosure at Great Zimbabwe UNESCO World Heritage Monument, Zimbabwe. (Photo from the University of Zimbabwe Archaeology Unit Archives)

Together with a few others, he was also one of the first trained archaeologists in the country. This set him up as a pioneer in many senses. He, however, surpassed the expectations of a pioneer, and he steered the discipline of archaeology in extraordinary directions, especially in the area of archaeological heritage management. He contributed significantly toward a more holistic management of archaeological heritage and cultural heritage in general. His pragmatic outlook of cultural heritage management has resulted in such approaches as the incorporation of local communities, the consideration of intangible aspects, and the acceptance of the concept of cultural landscapes as compared to cultural sites. He has passionately championed the need for social and economic beneficiation of communities that live with and around World Heritage sites and other significant cultural sites (Ndoro 2015a, 2017). He has also taken up the cause to see cultural heritage play a major role in solving conflicts around the continent by fostering cohesion and tolerance between and among community members (Ndoro 2016). All this has seen him become the face of African heritage management today.

Webber has contributed immensely to the training of archaeologists and heritage managers currently practicing in Africa. As they say, charity begins at home. Webber's contribution in germinating heritage management in Zimbabwe can never be overemphasized. At the university, he was instrumental in introducing heritage management courses to the archaeology curricular. In the early 2000s, he also spearheaded the introduction of a master's in heritage management that was to act as a training pool for not only Zimbabwean heritage managers but other managers from Southern Africa and beyond. He managed to inculcate urgency for heritage management in many of his students, a job he continues to do despite having moved outside of full-time academia over a decade ago. He has become a mentor even to the professionals since his approach to heritage management has always emphasized capacity building and skills development of local heritage practitioners across the continent.

Webber's major accomplishments are in finding workable solutions to heritage management in Africa. His work at Great Zimbabwe has had an immense impact on how archaeological sites and other World Heritage sites are managed. It also led to the proper management of other national monuments in Zimbabwe, especially those of the Zimbabwe culture. On the continental side, his pragmatic heritage management approaches have changed the attitude from one of just importing ideas from outside the continent wholesale into one that is result-oriented and based on the African culture and experience. He advocates for prioritizing traditional knowledge as solutions to some of the continent's perennial problems (Ndoro 2015b). He has helped in policy formulation at national and international level. As a member of and panelist at many of the meetings coordinated by organizations such as ICOMOS, ICCROM, and World Heritage committees, he

brought African heritage management issues to the attention of the world. His work with organizations such as the World Bank, UNESCO, and Getty Conservation Institute and heritage organizations from various countries has made sure that solutions for African heritage management challenges are found and implemented.

Many of the heritage management challenges in Africa were emanating from disfranchisement of the communities that live with heritage places. Ndoro brought one of the best solutions to these challenges by advocating for the employment of traditional management systems that communities have always used to look after the heritage places. He supported the concept of the community participation, in a way, which brings in a viable and less expensive heritage management systems. Community participation and the traditional management systems help lessen the burden for formal heritage institutions that cannot afford the financial resources required to look after heritage places in Africa.

One of the greatest legacies that Webber will eventually leave is in his publications. He has continued to write and co-author books, book chapters, and academic journal articles on archaeology and heritage management in Africa. He has also written material digestible by the general public (e.g., Pwiti and Ndoro 2014; Ndoro 2004). Any researcher dealing with heritage management in Africa should not overlook Webber's publications. His publications should be the first port of call for any student who is interested in heritage management, the management, and conservation of dry stonewalled monuments, community participation, or the role of culture in development and peace building.

As an acknowledgement of his enormous contribution to scholarship and professional heritage management, Webber has received a number of outstanding awards. He has been awarded African Diaspora World Tourism Award – for the promotion of African heritage places (2013) – and the prestigious 2015 ICCROM Award for his "outstanding contribution to the field of cultural heritage conservation." He has recently been awarded the Order of Civil Merit (commander) awarded by His Majesty the King of Spain (2017). The Association of Southern African Professional Archaeologists (ASAPA) has bestowed him honorary membership in recognition of his profound contribution to archaeological research and conservation in the region.

Neanderthals and Their Contemporaries

Trenton W. Holliday
Department of Anthropology, Tulane University, New Orleans, LA, USA
Evolutionary Studies Institute, University of the Witwatersrand, Johannesburg, RSA, USA

Introduction

The Neanderthals are the longest-recognized nonmodern humans known to science and are usually referred to their own species, *Homo neanderthalensis*. Geographically restricted to Europe and Western to West-Central Asia, fossil data suggest that they are contemporary with early members of our species (*H. sapiens*, or modern humans), as well as other nonmodern forms of the genus *Homo*. Genetic data suggest the Neanderthal lineage split from that of modern humans sometime between 800,000 and 300,000 years ago. However, most Neanderthal fossil specimens themselves have been recovered in Late Pleistocene contexts dating from ca. 130,000 to 30,000 years ago. Some scientists argue that the Sima de los Huesos sample from the Atapuerca Hills of northern Spain, which date to ca. 430,000 years ago, are Neanderthals, especially since genetic data link the two samples, but the Sima sample lacks many of the uniquely derived Neanderthal features.

Archaeologically, Neanderthals are most frequently associated with Mousterian tools, a Middle Paleolithic industry found in Europe, Western Asia, and parts of North Africa. However, late (ca. 32,000–36,000 years ago in radiocarbon years) Neanderthals in southwestern France (and likely Spain north of the Cantabrian Mountains) are associated with the Châtelperronian industry, which is typologically considered by archaeologists to be either a fully Upper Paleolithic or (more commonly) a transitional Middle-to-Upper Paleolithic industry. Neanderthals have also been thought to have been the makers of similar "transitional" Industries in Italy and Greece (the Uluzzian), and the Czech Republic, Slovak Republic, and Hungary (the Bohunician and Szeletian), but this view has recently come into question (see below).

Definition

Homo neanderthalensis is the fossil hominin species most closely related to our own species, *Homo sapiens* (modern humans). Neanderthals are distinguished from modern humans and other hominin species by a long-recognized suite of anatomical (and now genetic) characters, some of which are ancient retentions (*plesiomorphies*) shared with other nonmodern human species and others which are uniquely or shared-derived (evolved) characters (*apomorphies*). Ancient retentions in the Neanderthal skull include especially large shovel-shaped incisors (although in older adults the crowns of these teeth are extensively worn through paramasticatory use), long and low cranial vaults with pronounced brow ridges, prognathic (forward-projecting) faces that lack canine fossae but which have wide nasal apertures, and mandibles without a forward-projecting chin. Ancient retentions in the skeleton below the skull (i.e., the postcranial skeleton) include wide pelves with elongated public bones, strongly built and more horizontally oriented spinous processes in the cervical vertebrae, and the large, robustly built transverse processes of the lumbar vertebrae. Neanderthal ribs are also large and robust, and there are some data to suggest that the inferior aspect of their rib cage was less constricted (i.e., more open) than those of *Homo sapiens*, perhaps to accommodate the

wider pelvis. As was the case with earlier hominins, including members of the genus *Australopithecus*, the Neanderthal elbow joint evinces a relatively short ulnar coronoid process. Neanderthals (including Neanderthal infants) are also like earlier hominins in that they are characterized by limb bones with thickened cortical bone and smaller medullary (marrow) cavities. Neanderthal muscle attachment areas, particularly on the bones of the upper limb, are indicative of a heavily muscled physique; this, too, is a plesiomorphy retained from earlier *Homo*.

There are relatively few derived characters of the postcranial skeleton, the most noteworthy being a depression, or sulcus, along the axillary (lateral) border of the scapula corresponding to the scapular attachment of the teres minor muscle, one of the muscles of the rotator cuff. This sulcus tends to be found on the ventral, or rib cage, side of the scapula in *Australopithecus afarensis* (A.L. 288-1, or "Lucy"), *Homo erectus*, and *H. sapiens*, but in Neanderthals, it is almost exclusively found on the dorsal (back) side of the scapula's axillary border. Derived characters of the skull include size reduction in brow ridges, chewing musculature, and cheekbones relative to Early and Middle Pleistocene *Homo*, larger brains (in absolute terms Neanderthal brains are on average larger than those of *Homo sapiens*: 1350 cc for *H. sapiens*; 1520 cc for *H. neanderthalensis*), occipital buns, and a unique, ovoid depression of dubious function at the rear of the cranium known as the suprainiac fossa. Yet perhaps the most commonly cited distinctive anatomical feature of Neanderthals is their midfacial prognathism, i.e., the anatomical configuration in which the region of the face nearest the body's midline (primarily the nose and anterior dentition) is projecting. Projecting faces are also characteristic of earlier hominins, but Neanderthals differ from the ancestral condition in that the more lateral portions (or sides) of the face (predominately the zygomatics, or cheekbones) are in a more posterior position than would be typical for earlier members of the genus *Homo*. When considered as a whole, the morphological differences between the Neanderthals and our own species are quite marked (Figs. 1 and 2). In fact, multivariate analyses of craniofacial measurements consistently cluster the Neanderthals apart from *Homo sapiens* in multivariate space. In contrast, the differences among recent *H. sapiens* in craniofacial morphology are much smaller – this despite our own species' global distribution. It is of note that these anatomical differences between Neanderthals and modern

Neanderthals and Their Contemporaries, Fig. 1 Oblique views of the skull of (L to R) La Ferrassie 1 (*Homo neanderthalensis*) and Cro-Magnon 1 (*Homo sapiens*). The canine fossa is the depression visible under the orbits in the cheekbone area of Cro-Magnon 1. (Photo copyright John Reader)

Neanderthals and Their Contemporaries, Fig. 2 Schematic views of a male *Homo neanderthalensis* (L) compared with a male *H. sapiens* (R). (From Stringer and Gamble 1993)

humans are manifested despite the fact that the Neanderthal genome is over 99% identical to ours, indicating that perhaps only a few key changes in regulator genes differentiate the two taxa.

Historical Background

The first Neanderthal recognized as such was discovered at the (now obliterated) cave site of Feldhofer, in the Neander Valley (or "Thal" in nineteenth-century German) near Düsseldorf in 1856. Two other Neanderthals had previously been discovered, one at Engis, Belgium, in 1829 or 1830 and a second at Forbes' Quarry in Gibraltar in 1848, but neither of these specimens was recognized as a nonmodern form of human until decades later. Thus the term "Neanderthal" stuck as both the vernacular and scientific (*Homo neanderthalensis* King 1864) name for the human species represented by the individuals from Feldhofer and similar specimens from across Europe into Western to West-Central Asia.

Many scientists were at first reluctant to accept the Neanderthals as a prehistoric "race" or species of humans, even when further discoveries were made in Belgium at La Naulette in 1866 and in 1880 in what is now the Czech Republic at the site of Šipka. Among the most vocal critics was Prussian anatomist Rudolf Virchow, known as the "father of pathology," a staunch anti-evolutionist, who concluded that all of the newly discovered Neanderthal specimens were modern humans evincing various pathological conditions. Virchow's position became untenable after the

1886 discovery of two Neanderthal individuals at the Belgian site of Spy, which were preserved under an undisturbed stalagmitic layer and associated with both extinct mammals and "primitive" (Mousterian) stone tools.

Perhaps the most culturally salient Neanderthal individual was discovered in 1908 at the site of La Chapelle-aux-Saints in Corrèze in southwestern France. The relatively complete and well-preserved skeleton of this adult male individual was given to Prof. Marcellin Boule, who published a series of important articles on it from 1911 to 1913. In these articles, he took great pains to emphasize its "ape-like" nature (Fig. 3). Boule erroneously reconstructed the Chapelle-aux-Saints Neanderthal as having had a stooped posture, due in part to a perceived lack of modern humanlike spinal curvatures. Boule also reconstructed La Chapelle as having walked with a bent-kneed gait. It is to Boule whom we owe the popular conception (which still persists today) of the Neanderthal as primitive brute.

Over the course of the twentieth century and into the twenty-first, many more Neanderthal remains were discovered across Europe, which is widely regarded as the continent on which the Neanderthals evolved. Indeed, a number of Neanderthal features, including their foreshortened distal limb segments and wide bodies with voluminous, barrel-shaped rib cages (and even their large noses), have been argued to be the result of adaptation to the glacial cold of Pleistocene Europe. In Europe clearly diagnosable Neanderthal remains have been recovered in Belgium, Croatia, the Czech Republic, France, Georgia, Germany, Gibraltar, Greece, Hungary, Italy, the Netherlands, Portugal, the Slovak Republic, Russia, Spain, and Ukraine. The twentieth century also saw the discovery of multiple diagnosable Neanderthal skeletons in Israel, Iraq, Syria, and Uzbekistan. These European and Western Asian specimens have added greatly to our knowledge of Neanderthal anatomy and our understanding of their temporal and geographic range. Recently an anatomically nondiagnostic partial juvenile skeleton from Okladnikov Cave and a pedal phalanx from the nearby Denisova Cave in southern Siberia had Neanderthal mitochondrial DNA (mtDNA) sequences – extending the species' range to the Altai Mountains of southern Siberia (Fig. 4, and see below). Thus Neanderthals ranged from the Iberian Peninsula in the west across Europe into Western Asia and northwest up into southern Siberia. In contrast, no Neanderthals have been recovered from Africa, where almost all Neanderthal contemporaries, at least based on the fossil record (and not analyses of recent human DNA; see below), appear to be representatives of modern humans (*Homo sapiens*). Likewise, no Neanderthals are yet known from the Indian subcontinent or Eastern Asia. Neanderthal contemporaries in this region are variably referred

Neanderthals and Their Contemporaries, Fig. 3 Lateral views of crania of (L to R), a chimpanzee, La Chapelle-aux-Saints Neanderthal, and a modern human from one of Boule's publications. He emphasized the facial prognathism as a primitive feature aligning the chimpanzee with the Neanderthal. (From H.F. Osborn (1915) *Men of the Old Stone Age*)

Neanderthals and Their Contemporaries, Fig. 4 Map showing the approximate range of *Homo neanderthalensis*, including the recent discoveries from the Altai Mountains in southern Siberia. (From Krause et al. 2007)

to *H. erectus*, *H. floresiensis*, or *H. sapiens*, and possibly *H. heidelbergensis* (but see below).

Key Issues/Current Debates

The oldest question in the study of human evolution is that of modern human origins or the evolutionary emergence of our own species. Since the second half of the nineteenth century, this question has been intimately tied to the "Neanderthal question"; i.e., what role, if any, did the Neanderthals play in our own species' evolution? The last three decades saw the rise of competing models of modern human origins, with the multiregional evolution (MRE) and recent African origin (RAO) models representing diametrically opposing views. The MRE position, championed by Milford Wolpoff and colleagues, was that in the Middle and Late Pleistocene, genetic exchange between hominins across the Old World kept geographically dispersed populations of the genus *Homo* from differentiating to the point that they became separate species. Therefore, the origins of modern humans are not the origin of a new species, or a speciation event per se, but rather is simply the process of a global fixation of anatomical *characters* that we today recognize as "anatomically modern" – e.g., high, globular, rounded, crania, small brow ridges, forward-projecting chins, and non-projecting faces tucked beneath the frontal lobes of the brain. The MRE model also held that the Neanderthals made significant genetic contributions to the populations of modern humans who succeeded them in Europe and Western Asia. In contrast, RAO proponents, such as Chris Stringer, argued that the emergence of *Homo sapiens* was a cladogenetic (speciation) event, with modern humans evolving first in Africa ca. 200,000–300,000 years ago and then expanding to replace their nonmodern cousins in southern and northern Africa, the Levant, Eastern Asia, and ultimately Europe. Some RAO proponents argued that spoken language was unique to the newly evolved species and was ultimately the key to its/our success. However, since we now know Neanderthals had the derived, humanlike version of the *FOXP2* "speech and language"

gene, and given that Neanderthal basicranial, mandibular, and hyoid anatomy would not preclude human-like speech, and considering the large size of the Neanderthal brain, it appears unlikely that among the hominins only *Homo sapiens* could speak.

Many RAO proponents also argued that as separate biological species (following Mayr 2000), there was no successful interbreeding between *Homo sapiens* and *H. neanderthalensis*; rather the two species were reproductively isolated from each other. In other words, even if members of the two species recognized each other as potential mates, any resulting offspring of such unions were incapable of reproducing themselves, in much the same way as mules, the offspring of a horse mother and a donkey father, are almost always sterile.

Beginning in the 1980s intermediate models staked out the middle ground between the MRE and RAO approaches. In particular, the "Assimilation" model of Fred Smith and Erik Trinkaus (Smith 1994) and the "Replacement with Hybridization" model of Günther Bräuer (2008) agreed with the RAO position that modern humans evolved first in Africa, but unlike many RAO supporters, these workers saw paleontological evidence for varying amounts of successful interbreeding between *Homo sapiens* and nonmodern species of the genus *Homo*.

While paleontologists heatedly debated the issue of modern human origins for over 150 years, the question was ultimately answered in 2010 when the draft sequence of the Neanderthal genome was published (Green et al. 2010). Green and colleagues found that uniquely Neanderthal genetic sequences survive even today among non-African people, and they estimate that the proportion of Neanderthal ancestry in these non-Africans to be somewhere between 1% and 4%. It is notable that this finding is more in line with the predictions drawn from the "Assimilation" or "Replacement with Hybridization" models than with those made by either MRE or RAO. What remains a point of contention, however, is how to interpret this Neanderthal genetic contribution to (at least some) living humans. Does it represent multiple interbreeding events across Europe and Western Asia over the course of many millennia, or is it a remnant of extremely rare interbreeding that occurred only infrequently, perhaps only a few times in Western Asia? The fact that there is actual genetic evidence of interbreeding at least 30,000 years after it occurred suggests to many that the former is more likely than the latter.

Also related to this question (and still hotly debated) is the question of temporal overlap between Neanderthals and modern humans in Europe. The earliest directly dated, anatomically diagnostic, modern human in Europe is that of Oase, Romania, dated to 35,000 years BP (uncalibrated), and there are also tool industries which to date have only been associated with *H. sapiens* that date back some 40,000 years in Europe. Late Neanderthals are said to date to as recently as 32,000–33,000 BP (radiocarbon years) at the site of Vindija in Croatia, and some Mousterian deposits in southern Iberia are said to postdate 30,000 BP (although both sets of dates are disputed by some workers, some of whom argue that no Neanderthal is securely dated to later than 38,000 BP in radiocarbon years; e.g., Jöris and Street 2008). The late Mousterian dates, if accurate, would seem to indicate a temporal overlap of *Homo sapiens* and *H. neanderthalensis* in Europe of perhaps as much as 12,000 years. However, these dates fall at the very limits of the applicability of radiocarbon dating, and to further complicate matters, there is a radiocarbon plateau at ca. 35,000 BP. Perhaps more importantly, given the fluidity of material culture, tools should never be used as genetic markers – and in the archaeological record, we do have multiple examples of modern humans making and using Mousterian tools!

An additional potential geographical area of contact between *Homo sapiens* and *H. neanderthalensis* is the Levant, the region along the eastern shore of the Mediterranean. *Homo sapiens* is found in the southern Levant at ca. 100,000 BP, while *H. neanderthalensis* remains are found there dating to ca. 50,000–60,000 BP (Fig. 5). While some have interpreted these data as indicative of a period of 50,000 years of temporal overlap between the two species in the region, this

Neanderthals and Their Contemporaries, Fig. 5 The skull of the Amud I *Homo neanderthalensis* specimen from northern Israel, dated to ca. 50,000 years ago (above), compared with the Skhul V *H. sapiens* specimen from northern Israel, which likely dates between 100,000 and 80,000 years ago. (Photo copyright Israel Antiquities Authority (Jerusalem) and Dr. Eric Delson)

is unlikely to be the case. Since we now know that Neanderthals and modern humans were at least somewhat interfertile, the notion that they could live side by side in a small area like the southern Levant for tens of millennia, while remaining biologically distinct populations is extremely improbable. What seems much more likely is that the two hominin species were in the region at different times and under different climatic regimes. Specifically, it appears that *Homo sapiens* expanded out of Africa and into the Levant during the relatively warmer climes of the Last Interglacial and later retreated back into Africa as the climate deteriorated with the onset of glacial conditions at ca. 75 ka (MIS 4). Likewise, as has been argued for many years by Bernard Vandermeersch (1981) and others, the Neanderthals may not have been in the Levant prior to 75 ka and perhaps only expanded into the region from Europe (and/or from the region [s] surrounding the Caucasus Mountains and Caspian Sea) with the onset of deteriorating climatic conditions in the north. Analyses of microfauna by the late Eitan Tchernov support this conclusion, since he found that the small mammal faunal (microfaunal) remains from the Levantine *Homo sapiens* site of Qafzeh have a broad and distinctive Afro-Arabian component, while later microfauna associated with *Homo neanderthalensis* (or at least with cultural remains assumed to be associated with that species) at sites such as Tabun and Hayonim are characterized by many fewer Afro-Arabian elements and a much greater number of Palearctic species (Tchernov 1998). Based on zooarchaeological data, then, contacts between the two species were likely relatively fleeting in the southern Levant.

Another unresolved issue concerning the Neanderthals and their contemporaries is that of the emergence of "modern" behavior and whether the Neanderthals were themselves capable of it. The issue of behavioral modernity has its roots in the archaeological study of the Middle-to-Upper Paleolithic transition in Europe. Viewed through a European lens, the Upper Paleolithic, which begins to appear ca. 40,000 years ago in Europe, represents the high-water mark of Paleolithic culture. In the Upper Paleolithic, we have the first-time appearance (in Europe, at least) of large numbers and types of bone and antler tools, particularly those made in such a way as to take advantage of bone's special properties, such as barbed harpoon points. Complex rock-lined fireplaces complete with ventilation systems replace simple Middle Paleolithic hearths. Vivid and realistic cave paintings, and mobile art in the form of small sculptures, also make their first appearance in the Upper Paleolithic, and there is also a technological shift in the Upper Paleolithic toward stone implements made on long parallel-sided blades. This suite of technological and artistic characters came to be viewed by archaeologists as the "total package" indicative of "modern" human behavior. In contrast, the

preceding European Middle Paleolithic industry (the Mousterian) had virtually no evidence of art, with stone tools made on Levallois and other pre-prepared flakes that were only occasionally blades. Likewise, the Mousterian had very few bone and antler tools. Archaeologists and biological anthropologists alike, then, interpreted the Middle-to-Upper Paleolithic transition as indicative of the work of two different types, or species, of hominin. The Middle Paleolithic (Mousterian) tools were the work of Neanderthals, who lacked the cognitive capacity to make art or complicated tools. The Upper Paleolithic, then, with its art and technological complexity, was exclusively the work of modern humans. This perspective hit a stumbling block when in 1979 a Neanderthal skeleton was unearthed from Châtelperronian levels at the French site of St.-Césaire. Up until that point, archaeologists had considered the Châtelperronian to be (typologically, at least) an Upper Paleolithic industry. Could the Neanderthals be capable of making Upper Paleolithic tools after all? Further analyses revealed that previously nondiagnostic human remains from Châtelperronian levels at the French site of Grotte du Renne at Arcy-sur-Cure were also Neanderthal, and these specimens were also associated with evidence of personal adornment in the form of pierced animal teeth.

Some workers responded to this "problem" by demoting the Châtelperronian (and similar industries such as the Szeletian, Bohunician, and Uluzzian) from truly Upper Paleolithic industries to "transitional" Middle-to-Upper Paleolithic industries. Many also came to view these "transitional" industries as a kind of Neanderthal response to the superior technology brought into Europe by "invading" modern humans. In other words, the Upper Paleolithic-type tools found in the Châtelperronian were either manufactured in imitation of modern humans' technology or, alternatively, were acquired by Neanderthals via trade with modern humans. Archaeologist Paul Mellars (2005) goes so far as to invoke the timing of the appearance of these transitional industries as evidence that the Neanderthals borrowed these technological innovations from modern humans. He notes that Neanderthals used nothing but Middle Paleolithic tools until the relatively sudden appearance of transitional industries ca. 40,000 years ago – a date too coincidentally correlated with the first appearance of anatomically modern humans in Europe not to be causally related to them.

Archaeologist João Zilhão (2006) disagrees, arguing instead that the Châtelperronian and similar industries were autochthonous developments with their technological roots in the preceding local Mousterian. He and his colleagues also argue that given taphonomic processes and the error ranges inherent in radiometric dating, one cannot reject the null hypothesis that the Châtelperronian is older than the Aurignacian (the industry argued by many archaeologists to be the earliest "truly" Upper Paleolithic industry in Europe) at every site that contains both industries. Zilhão also argues that since there is some (albeit relatively rare) evidence for art in Mousterian contexts at multiple European (and therefore presumed Neanderthal) sites, and given the fact that some hunter-gatherers in the ethnographic present manufacture simple lithic technologies and/or make no art on durable materials (i.e., their art would be "archaeologically invisible"), one cannot create a definition of "modern" human behavior that does not either (1) include Neanderthals or (2) exclude some groups of living humans. This debate has also become a bit more complicated when it was revealed that deciduous molars, said to be derived from Uluzzian levels in Italy, cluster in multivariate space with modern human deciduous molars, and not those of Neanderthals (Benazzi et al. 2011).

Some researchers criticize the traditional definition of modern human behavior by arguing that the "trait list" approach to defining "modern" behavioral characteristics is Eurocentric and ignores the archaeology of other regions, especially Africa, where arguably many "modern" behavioral characters first appear in Middle Paleolithic (Middle Stone Age, or MSA) contexts (McBrearty and Brooks 2000; Shea 2011). Others posit that the behaviors traditionally viewed as "modern" are most likely outgrowths of shifts in climate, resource intensification, or even population density (Henshilwood and Marean 2003). Recently, one researcher has even called for an

end to the use of the "behavioral modernity" concept altogether (Shea 2011), but given the fascination we humans have for what makes us unique, this issue is unlikely to go away anytime soon.

A final notable area of debate surrounding the Neanderthals involves how many species of hominin coexisted with them. Recently, new excavations at the Moroccan site of Jebel Irhoud uncovered modern (or nearly modern) *H. sapiens* fossils dated by thermoluminescence (TL) and electron spin resonance (ESR) to ca. 250,000–350,000 years ago (Richter et al. 2017). Other early modern humans from North Africa dating to ca. 100,000 years ago include fossils from Dar-es-Soltan and Grotte des Contrebandiers. In East Africa nearly modern *H. sapiens* from Omo Kibish and Herto in Ethiopia date to ca. 190,000–160,000 years ago, while in the southern Levant (at sites such as Qafzeh and Skhul) and southern Africa (at sites such as Klasies River Mouth), these hominins date to ca. 120,000–100,000 years ago. All of these dates make early *H. sapiens* contemporary with *H. neanderthalensis*, and interestingly, these modern humans, like most Neanderthals, are associated with Middle Paleolithic (MSA, Mousterian, or Aterian, depending on the region in question) tools.

Yet how many other species of hominin might also be contemporary with the Neanderthals? As mentioned above, at Denisova Cave in the Altai Mountains of southern Siberia, mtDNA taken from a pedal phalanx identify the specimen as Neanderthal. However, genetic data from a manual phalanx and molar recovered from the same site are argued to be from a previously unknown species of hominin, referred to as "Denisovans." Genetic sequences of living Africans reveal introgression from a presumably extinct species of African hominin previously unknown to science, and this species is thought to have been contemporary with Neanderthals (Lachance et al. 2012).

In terms of fossil data for the contemporaneity of other hominin species with Neanderthals, recent discoveries at the site of Lingjing in the Henan province of China of fossil hominins dating to ca. 105,000–125,000 years ago (Li et al. 2017) are of interest because while they are not fully Neanderthal in morphology, they nonetheless have some Neanderthal characters, prompting some to suspect that they might represent the so-called Denisovans. Thus far, no DNA has been successfully extracted from these specimens. Earlier specimens from China include material from Jinniushan (dating to ca. 280,000–250,000 years ago) and Dali (dating to ca. 230,000–180,000 years ago) that may be contemporary with the earliest Neanderthals, although they are likely older than most (if not all) of them. Neither specimen shows any uniquely derived Neanderthal characters, and some researchers refer the specimens to *Homo erectus* (Dali's cranial capacity [ca. 1120 cc] is close to the *H. erectus* mean). However, both specimens are derived enough that they do not easily fit within the *H. erectus* hypodigm. Jinniushan's cranial capacity (ca. 1400 cc), for example, is higher than the modern human mean, and while Dali's face is badly distorted, its neurocranium is decidedly less so, and the shape of its cranial vault is much more derived than what is typically considered *H. erectus*-like. Similarly, the Late Pleistocene (ca. 150,000–100,000 years ago) Chinese Maba (Mapa) partial cranium is likewise considered by many to be too derived in its morphology to be referred to *Homo erectus*. The question as to which taxon it does belong, however, is much more complicated. The specimen does not preserve any uniquely Neanderthal characters, nor does it appear to be derived enough to warrant inclusion in *H. sapiens*. One possible taxonomic assignment for Jinniushan, Dali, and Maba is *Homo heidelbergensis*, but many reserve this name for European and/or African Middle Pleistocene specimens only. Another possibility, as mentioned above, is that at least some of these specimens represent the population known as "Denisovans." Yet another option is to refer these hominins to "archaic" *Homo sapiens*, but this term is problematical for two reasons. First, as was pointed out by F. Clark Howell, nowhere else in plant or animal taxonomy is a qualifier put before a species name; a specimen or subpopulation either belongs to a species, or it does not. The second problem is that "archaic" *H. sapiens* is somewhat vague in meaning, since this term has been used to describe modern human specimens from Qafzeh and

Skhul, and even the Neanderthals themselves! Milford Wolpoff solves this (and similar) dilemmas by sinking all specimens assigned to the genus *Homo* from all continents over the last 2.0 million years into *Homo sapiens*. From the perspective of Ernst Mayr's biological species concept, he is on solid ground in so doing, since most likely all member species of the genus *Homo* would have been interfertile – i.e., capable of producing "hybrid" offspring that could themselves reproduce (Jolly 2001; Holliday 2006). Wolpoff's taxonomic scheme ignores interesting and important biological variation, however, and would make the discussion and teaching of human evolution difficult, at best.

Another locale where multiple fossil hominins have been recovered since the end of the nineteenth century is the Indonesian island of Java. While its dating remains problematic, the site of Ngandong in Java has long been thought to be ca. one million years later than other *Homo erectus* sites on the island, and while the Ngandong crania show larger braincases on average than early Javanese *H. erectus*, paleoanthropologist Susan Antón has shown that in all other aspects of their cranial morphology, the Ngandong crania are quite *Homo erectus*-like. Beginning in the mid-1990s, the Ngandong remains were even thought by some to date to the Late Pleistocene, although a Middle Pleistocene age now seems much more likely (Indriati et al. 2011). Such a date could make the Ngandong *H. erectus* specimens contemporary with the earliest Neanderthals (although they likely antedate most Neanderthals).

Also in Indonesia, a find of great importance was the 2004 discovery of diminutive hominin specimens from the site of Liang Bua on the island of Flores, where at least one small-brained individual dating to the Late Pleistocene (ca. 60,000–100,000 years ago) evinces cranial morphology similar to both 1.9 million-year-old *H. habilis* from Africa and 1.7 million-year-old *H. erectus* fossils from Dmanisi in Georgia (Fig. 6). While not universally accepted by the scientific community, this specimen and other less complete specimens from Liang Bua have over the last few years become more widely viewed as representative of a late-surviving descendant species of the earliest *Homo* that expanded beyond the African continent: *Homo floresiensis* – a very "primitive-looking" species contemporary with *Homo neanderthalensis*.

More recently, another "primitive" species of the genus *Homo*, *H. naledi*, was uncovered in a seemingly deep cave context in the Rising Star cave system in South Africa (Berger et al. 2015). With an average cranial capacity of ca. 500 cc, the specimen is not much more encephalized than *H. floresiensis* and is generally less encephalized than *H. erectus*. Surprisingly, the deposits in which the *H. naledi* material was recovered, as well as some of the *H. naledi* teeth themselves, were dated by Uranium-Thorium, paleomagnetic, and ESR methods to a fairly recent date of ca. 236,000–335,000 years ago (Dirks et al.

Neanderthals and Their Contemporaries, Fig. 6 Lateral view of casts of 1.9 million-year-old KNM-ER 1813 (*Homo habilis*), 1.7 million-year-old Dmanisi 2700 (*H. erectus*) and 60,000–100,000-year-old Liang Bua 1 (*H. floresiensis*). Despite the difference in dates, the crania are remarkably similar in size and morphology. (Photo credit: Chris Stringer, Natural History Museum, London)

2017). These dates, while controversial, could make *H. naledi* contemporary with the earliest Neanderthals.

Future Directions

Discoveries of Neanderthals are still being made at sites across Europe and Western Asia, and one trend that is likely to continue is one begun at the site of El Sidrón in Spain. Here Neanderthal DNA has been recovered, and so archaeologists excavate there in clean-room gear in order to minimize the chances of contaminating fossil DNA with that of recent humans (Fig. 7). In addition to the ongoing international effort to isolate more Neanderthal DNA from existing (and future) fossil finds, genetic researchers such as John Hawks and Laurent Abi-Rached are sorting through the many millions of base pairs of Neanderthal DNA in the draft sequence, searching for evidence of the action of selection on the Neanderthal phenotype, and trying to understand the nature of the Neanderthal genetic contribution to living people. Other scientists, such as Robert Franciscus, are using animal models and 3D morphometrics to better understand the developmental pathways involved in growing a projecting Neanderthal face vs. a non-projecting modern human one. Scientists like Michael Richards and colleagues are exploring Neanderthal diets by examining stable carbon and nitrogen isotopes isolated from their bone collagen. These data indicate that at least some European Neanderthals ate a primarily meaty diet and that most of their dietary meat came from terrestrial herbivores. More data on Neanderthals from a wider geographic area would be welcome, and future work with oxygen and strontium isotopes isolated from Neanderthal tooth enamel has the potential to tell us if diet changed during growth and development and even how far individual Neanderthals (or their contemporaries) ranged during their lifetimes. Did Neanderthals, for example, tend to remain in the local area of their birth, or did they frequently venture much farther afield? Finally, researchers like John Shea and Steven Churchill are gathering new experimental data using living human subjects to more fully explore just how Neanderthals used their upper limbs, and armaments, in hunting – is the long-distance throwing of spears, for example, a modern human innovation, one Neanderthals lacked? All of these approaches are likely to prove fruitful over the coming decades as scientists endeavor to learn more about humanity's closest fossil relatives.

Near East (Including Anatolia): Geographic Description and General Chronology of the Paleolithic and Neolithic

Aaron Jonas Stutz
Department of Anthropology, Oxford College of Emory University, Oxford, GA, USA

State of Knowledge and Current Debates

Introduction

The Near East is situated at the crossroads between the genus *Homo*'s African evolutionary core and the Eurasian periphery (Fig. 1). The Paleolithic and Neolithic prehistory of the Near East is literally central for understanding the genus *Homo* as a globally distributed lineage, whose single surviving species – *Homo sapiens* – continues to shape and be shaped by the terrestrial, omnivorous, extractive, and socially intensive niche with which it has coevolved. This essay examines the general theoretical issue of biocultural evolution in the context of Near Eastern geography, climate, ecology, and Stone Age prehistory. In doing so, it offers an overview of Paleolithic and Neolithic paleoanthropology and archaeology, with basic introductory information about industries, technocomplexes, fossils, and key sites in chronological context.

The Paleolithic begins with the late Pliocene emergence of Lomekwian hammer-on-anvil chipped stone technology (ca. 3.3 million years ago [mya]) in East Africa, followed by the oldest freehand Oldowan chipped stone technology (Harmand et al. 2015). The oldest well-documented Oldowan occurrence outside of Africa comes from Dmanisi, on the northern margin of the Near East, but a small Oldowan surface assemblage, likely associated with the Erq al-Ahmar formation in the Jordan Valley, Israel, would be roughly contemporaneous, ca. 1.80 mya. The Paleolithic continues until the end of Pleistocene (ca. 11.7 thousand years ago [kya]). The Prepottery Neolithic of the Near East then stretches from the Pleistocene-Holocene

Near East (Including Anatolia): Geographic Description and General Chronology of the Paleolithic and Neolithic, Fig. 1 Regions and locations in the Near East that are key for understanding the geographic structure of human dispersals and population interaction in the Pleistocene and early Holocene

transition to ca. 8.20 kya. Figure 2 is a timeline summary of Pleistocene-Holocene prehistory in the region.

Across the vast temporal extent of the Paleolithic, the Near East exhibits a continuous – or nearly continuous – record of human occupation (Bar-Yosef 1980), but paleoanthropological interest in the region emphasizes how it contains migration or dispersal corridors linking East and North Africa to western and southern Eurasia (Groucutt et al. 2015). The Paleolithic settlement of the Near East was recurrently shaped by African population expansions into the region, in turn shaping further population waves into the rest of Eurasia. The inference of repeated out-of-Africa (OOA) Pleistocene range expansions is broadly empirically based on human fossil and archaeological evidence, thoroughly backed up

Near East (Including Anatolia): Geographic Description and General Chronology of the Paleolithic and Neolithic, Fig. 2 Key evolutionary periods, hallmarks, and archaeological technocomplexes/industries in the Pleistocene and early Holocene prehistory of the Near East

N

by geographic analyses of ancient and extant genomic variation. By virtue of the region's supracontinental geographic setting, the human occupation of the Near East must have shaped these OOA range expansions, but very importantly, there is still considerable debate over the environmental context and systemic biological and cultural causes. This debate is vital for ongoing research on three chronologically successive hallmark developments:

- The initial human expansion out of Africa in the Lower Pleistocene (ca. 2.6 mya – 0.78 mya)
- The spread of modern human anatomy out of Africa, across the Middle-Late Pleistocene transition (marine isotope stages 5–6, ca. 170–80 kya)
- Following a later Middle Paleolithic episode in which European Neandertal anatomy spread into the Near East (ca. 80–50 kya), the decisive expansion of Upper Paleolithic technology – associated with modern human anatomy – in the Late Pleistocene (ca. 50–20 kya)

In addition, *the transition from the final Paleolithic – known in the region as the Epipaleolithic – to the Neolithic (seen at a long-term scale from* ca. *20 kya – 8 kya) is often viewed through the lens of the transition to sedentism, agriculture, and village life, which emerged "full-blown" in the Prepottery Neolithic B period of the Near East*. Notably, the Near Eastern case may represent the earliest primary prehistoric transition from a hunting and gathering subsistence mode

to a predominantly agricultural one (Bar-Yosef 1998a; Sherratt 2007).

The theoretical emphasis in this essay is on a complex systems evolutionary approach for considering the debates and open questions surrounding the Near East's crossroads setting for recurrent, supracontinental, biocultural change during the Stone Age. It is emphasized that new scientific insights, novel questions, and critical humanistic concerns and lessons drawn about Near Eastern prehistory must rely on interdisciplinary integration of evolutionary biology, ecology, environmental science, and diverse social science frameworks, including both quantitative and interpretive cultural approaches.

Near Eastern Geography, Climate, and Ecology in the Pleistocene and Early Holocene

The Near East is generally considered to encompass a large portion of Southwestern Asia, including the following key subregions: the eastern Mediterranean Levant, the Arabian Peninsula and adjoining Transjordanian and Syrian plateau semiarid zones, Mesopotamia, the arc of the Taurus-Zagros Mountains, the Taurus-Zagros foothills, and the Anatolian peninsula (see Fig. 1). The Near East is geographically conspicuous as the link between Africa and the rest of Eurasia, placing it at the center of the largest contiguous landmass that has existed since the Pliocene.

Major Geographic Structure of the Near East

In identifying and understanding the paths that ecologically connect Africa with Eurasia, paleoanthropological research has focused on how overall geographic structure has shaped a persistent climatic and phytogeographic pattern among the major regions that comprise the Near East. In general, the Levant is relatively well watered by a

Near East (Including Anatolia): Geographic Description and General Chronology of the Paleolithic and Neolithic, Fig. 3 Selected Lower and early Middle Paleolithic (LP and MP) sites in the southern Levant. highly seasonal, westerly winter monsoon system. This has yielded a robust Mediterranean environment extending west-east, from the coast to the Transjordanian and western Syrian plateaux. The Anatolian plateau and much of the Taurus-Zagros arc, with their higher elevations, also receive substantial precipitation, but the combination of a more continental Eurasian setting and higher altitudes notably results in colder winter temperatures and, often, snowfall. The Arabian Peninsula is arid, with a band of semiarid steppe extending in an arc from the Transjordanian and Syrian plateaux across Mesopotamia. The Near East is dominated, then, by semiarid or arid habitats. However, the Tigris-Euphrates valley in Mesopotamia has a geomorphological history that can be traced to the late Pliocene (Yacoub 2011), and substantial geological basins in semiarid zones – including El Kowm in Syria and Azraq in Jordan – have supported strongly flowing springs and widespread wetlands from at least the Middle Pleistocene onward. In these areas that otherwise received very little precipitation, stable hydrological features ensured permanent freshwater corridors and oases. This would have made the entire zone from Arabia to Mesopotamia attractive for mobile hunter-gatherer groups. In fact, as Rose (2010) has detailed, the Persian Gulf Basin would have been a wetland for large stretches of the Pleistocene, fed by strong freshwater springs. Even when prevailing climatic conditions were at their driest (occurring during the most extreme hot and cold hemispheric or global episodes), predictable major wetlands and riverine corridors would have persisted across the Arabian and Mesopotamian zones.

Recently, researchers have more broadly emphasized just how important this geographic structure has been for Pleistocene human evolution (Groucutt et al. 2015). Rich alluvial systems or wetland basins situated in extensive semiarid or arid regions characterize not only the Arabia-Mesopotamia-Persian Gulf Basin region but also the entirety of North Africa. The sub-Saharan African geographical core zone of human evolution has been linked to Eurasia via this supra-continental arid/semiarid belt that was conspicuously dissected and dotted by major permanent rivers and oases. When human populations were growing or at prevailing carrying capacity in sub-Saharan Africa, forager groups would have budded off, almost always able to exploit predictably located resource-rich habitats along the Nile drainage, in North African oases, or along Arabian coastal zones accessible via Bab al-Mandeb (see Fig. 1). A high-mobility hunter-gatherer strategy of movement along rivers and coasts and between spring-fed wetland basins would have involved long-distance moves along rich corridors embedded in an otherwise ecologically impoverished desert/steppe belt. Quite simply, the high contrast in ecological productivity between rivers and wetlands, on the one hand, and desert and semiarid steppe, on the other, would have essentially funneled mobile hunter-gatherers from the sub-Saharan African core to the Eurasian periphery in Pleistocene human evolution. It should be noted that occasionally, this very same structure would have supported funneling hunter-gatherer migration from Eurasia into sub-Saharan Africa, but paleoanthropological and genetic evidence overwhelmingly suggests that sub-Saharan Africa was a dominant net population source for migration throughout most of the Pleistocene (Mallick et al. 2016; Pagani et al. 2016).

N

The Near East and Climate Change

Human prehistory in the Near East, of course, has not simply been determined by the basic geographic structure of environmental variation. Biocultural evolution in the genus *Homo* has been a complex systemic process, and an important environmental dimension of the complex biocultural systems evolution has involved major global or Northern Hemisphere Pleistocene and early Holocene climate changes. These climate dynamics have driven fluctuations in boundary locations and in the scale of difference in seasonality and ecological productivity between adjacent habitat zones. Again, these include the Arabian-Mesopotamian arid/semiarid belt, the Levant, the Taurus-Zagros foothills, the Taurus-Zagros Mountain arc, and the Anatolian plateau.

The Pleistocene and early Holocene periods were marked by recurrent swings in prevailing temperature and rainfall levels, unfolding at scales

from centuries to millennia, and this environmental dynamism was only magnified by the Near East's geological and climatic complexity. The region is situated at the confluence of still active tectonic trends, reflecting a relatively ancient collision of the Arabian plate with Eurasia, resulting in closure of the Tethys Sea and formation of the Taurus and Zagros mountains, the more recent Miocene formation of the Mediterranean Basin, and the Pliocene onset of rifting from East Africa to the Levant. The region's climate is dominated – from south to north – by the Saharo-Arabian desert belt, westerly Mediterranean monsoon systems, and westerly continental systems. Yet, because of the region's tectonic history, we see striking topographic and geological variation in the Levant, Anatolia, and the Taurus-Zagros mountains. This has generally meant that within and between the subregions comprising the Near East, gradients between warmer and cooler and wetter and drier climatic patterns could be especially sharp, well within a day's walk. During generally warm and humid hemispheric or global climatic swings, the Near East would have had an especially high proportion of ecotonal habitat, with immediate access to rich forest, gallery forest, wetland, and grassland plant and animal food resources. During cool and dry climatic episodes, well-watered lower-elevation regions – conspicuously including the southern Levant, the narrow northern Levantine and Anatolian coasts, and the Taurus-Zagros foothills – would have been important ecological refugium zones within the larger region. These refugium subregions would have maintained substantial year-round plant and animal resource diversity in a mosaic of forest, grassland, wetland, and littoral habitats. Moreover, the zones adjoining major rivers – notably the lower courses of the Tigris and Euphrates – and wetland basins in semiarid habitats sometimes experienced grassland soil development during moderately cool periods. This is because atmospheric precipitation increased, while riverine and lacustrine evaporation rates fell. Such periods included portions of marine isotope stages 4 and 3 (including the intervals ca. 75–50 kya and 40–30 kya) (Torfstein et al. 2013). Paths between year-round refugia – including the southern Levant – and wetland patches nestled in adjacent semiarid subregions would have become more stable and ecologically productive during moderately cool episodes. While it is currently possible to sketch the pattern of ecological connections between subregions under recurrent Pleistocene climatic fluctuations, their complexity makes it an outstanding challenge to link specific climate changes to particular developments in human biocultural evolution.

Microenvironmental Variation Within and Between Near Eastern Subregions

Indeed, ongoing research continues to provide striking detail about variation in past Near Eastern environments. In this section, the resulting significant microenvironmental variation – observed at multiple scales between 1 and 1000 km – is examined more closely. For instance, the west-east geological and topographic structure of the Mediterranean Levant is generally similar from south to north – with coastal hills or mountains, interior valleys, a western rift escarpment mountain range, a deep rift valley, and an eastern plateau. Yet, if we compare the southern portion (roughly from the Gaza coast to the Israel-Lebanon border) to the northern portion (roughly from southern Lebanon to the Syria-Turkey border), it may be emphasized that the slightly higher latitude and substantially higher elevation of the Lebanon Mountains increase the role of snowfall and snowmelt on water availability (through spring and lake formation), vegetation patterns, and landscape stability and erosion dynamics, when compared to the southern Levant. Moreover, the higher elevation of the Bekaa portion of the rift valley – when compared to the Jordan Valley-Dead Sea basin to the south – entails substantially colder, often inhospitable winter conditions. Thus, although the southern Levant also exhibits dramatic microenvironmental variation, often over very short distances, we see relatively warmer winter temperatures from the broader Mediterranean coastal plain, across the lower interior hills and mountains, into the much deeper rift valley (the Jordan and Dead Sea basin), to the Transjordanian plateau. The result is less temperature seasonality and

greater overall environmental productivity in the southern than in the northern Levant.

It is instructive to consider how this example of subregional environmental variation would have been significant for hominin foragers over distances of 10s to 100s of kilometers, well within the range of macroband or dialect group territories of ethnographically or ethnohistorically documented hunter-gatherers. Such geographic variation may be most clearly appreciated for Lower and Middle Pleistocene OOA expansion episodes, which – according to all available evidence – predated the adoption of tailored clothing and rigid footwear technology. Modern human thermoregulatory adaptations – in the absence of effective insulating technological solutions – allow us to withstand sustained prevailing temperatures no lower than 0 ° C without suffering physiological consequences that have immediate- or long-term stress-related fitness effects. Neandertals and cold-adapted modern humans, with shorter limbs and short but wider torsos, would only have achieved limited adaptive benefits, slightly pushing the low-temperature tolerance level or increasing endurance under conditions of marginal balance between energy intake and heat loss. Of course, clinal selection for thermoregulatory adaptation across latitudinal gradients – even in the face of extensive gene flow – is well documented for contemporary humans. Still, even cold-adapted human populations – including Neandertals – would not have been able to sustain extended activity in subfreezing winter daytime conditions without insulating clothing (White 2006). At higher elevations substantially more habitat in the northern Levant would have had subfreezing winter conditions for much of the Pleistocene. During extreme hemispheric or global cold climatic episodes, the cold-season duration and spatial extent of such habitat would have increased more in the northern than in the southern Levant. Thus, during the warmer spring, summer, and fall seasons, the northern and southern Levant alike would have provided abundant freshwater sources and diverse large animal, small animal, and high-quality plant (fruit, seed, tuber, and nut) resources. Yet, the southern Levant would have encompassed more winter refugium habitat, as well as more easily passable long-distance west-east corridors to rich permanent lakes, wetlands, and springs in the semiarid or arid zones that extend from the Arabian Peninsula northward to Mesopotamia (including important permanent oases with deposits stretching back to the Middle Pleistocene, such as the Azraq, Jordan, and Ain Hummal, Syria).

For much of the Pleistocene, then – from the earliest expansion of the genus *Homo* out of Africa to the onset of the Upper Paleolithic – local hominin carrying capacities in the Near East would have been limited, not only by average annual environmental productivity and water availability but also by winter temperature and snow cover. More specifically, if winter represented the season during which per capita hominin energy and nutrient balance (calories and vital nutrients in vs. out) reached an annual minimum, then carrying capacity would have been especially strongly limited by seasonality on a subregional scale in the Near East. This would have had a vital implication, in turn, for the hominin behavioral dynamics shaping colonization and range expansions out of Africa and into Eurasia via the Near East. The subregional diversity seen throughout the region – exemplified by the northern vs. southern Levant's latitudinal and topographic differences – entails that seasonal winter zones of relatively high temperature and ecological productivity would have been localized centers of higher hominin population density and social interaction intensity. Topographically accessible paths between such winter refugia would also have been particularly important for relieving seasonally concentrated social scalar stress, or for maintaining social relationships and sharing information for reducing risk across a wider territory.

Winter refugium subregions – with relatively high moisture and limited winter cold temperatures – would include most of the southern Levant, coastal areas of the northern Levant and Anatolia, and the middle Tigris-Euphrates valleys and lower Taurus foothills. In semiarid or arid areas, more localized winter refugia would have existed at major oases, inland lakes, and wetlands. During Pleistocene periods

of lower sea level, the basin that is now the Persian Gulf would have been a much larger marshland or delta landscape, potentially becoming an additional refugium. The lower Tigris-Euphrates valleys would have provided a rich year-round corridor, cutting through a semiarid zone, connecting the lower Mesopotamian/Persian Gulf delta and middle Tigris-Euphrates refugia. Populations in the Mediterranean and Negev-Sinai semiarid zones in the southern Levant would have been connected to much of Arabia and Mesopotamia – via long-distance residential mobility or long-term demographic migration, through a network of seasonally wet wadis, wetlands, and lakes (Groucutt and Petraglia 2012).

Environmental Implications for Human Evolution

This seasonality-based human evolutionary ecology framework sets up a strong expectation that, although the Mediterranean zone and rift basin in the southern Levant would have provided the richest winter refugium zone just outside of Africa, this well-studied subregion's own prehistory cannot be understood without exploring in greater detail how it is interconnected with the rest of the Near East. At the same time, of course, increasing research interest in the Arabian Peninsula should continue to be contextualized within the broader Near East, too. Recent arguments may be correct that the Bab al-Mandeb-Arabian Coast was a more important long-term physical connector between Africa and Eurasia than was the Nile Valley-Sinai-southern Levant. However, the evolutionary ecology of hunting and gathering in the terrestrial, omnivorous, extractive, and socially intensive human niche carries some necessary implications for understanding human population dynamics. Recurrent prehistoric demographic migration streams or expansion waves beginning in Africa and spreading via the Near East into Eurasia would have unfolded over millennial scales, as migration or wave-front advance rates resolved across multiple generations. In order for any mobile Near Eastern hunter-gatherer population to feed such sustained intergenerational demographic growth, it would have to exhibit ecologically resilient socio-technological adaptations across multiple subregional and regional phytogeographic zones.

It is arguably the case that some prehistoric research has focused too much on quibbling over alternative compelling narrative-driven hypotheses – such as Nile Valley-southern Levant vs. Bab al-Mandeb-Arabian Coast as main dispersal corridor, or fast versus slow OOA expansions. It may be more theoretically appropriate – considering the geographic-environmental structure of the Near East – for researchers to work more explicitly with a regional dynamic complex systems framework. Smaller-scale shifts in residential mobility strategies, shifts in the geographic distribution and size of social networks, and intergenerational migration-dispersal episodes would have sustained the broader trends of expansion into Eurasia by unfolding at centennial or millennial timeframes within the Near East, mainly among:

- *Richer winter refugia* – the southern Levant, the narrower coastal patches of the northern Levant and Anatolia, and the Middle Tigris-Euphrates valleys/southern Taurus-Zagros foothills
- *Winter refugium corridors or patches embedded in semiarid and arid zones* – most notably the Lower Tigris-Euphrates valley and Persian Gulf Basin, along with stable or fluctuating wetlands, rivers, and streams across Syria, Jordan, southern Mesopotamia, and the Arabian Peninsula
- *Ecologically rich zones that are inhospitable for at least a month or more in winter* – including higher-altitude portions of the northern Levant, much of the Anatolian plateau, and the Taurus-Zagros mountains

This framework is important, in part, because it allows us to model Pleistocene biocultural evolution in the Near East at a finer scale and more accurate level of complexity. While climate change is still considered a critical factor for evolutionary and behavioral change, it is recast from being a primary factor, such as simply forcing the development or disappearance of additional green corridors across the North African-Arabian arid

belt. It becomes, instead, an exogenous long-term variable affecting the position of ecological boundaries and the overall ecological differences between adjacent subregions – with the biocultural evolutionary implications varying under prevailing conditions of demography, biological variation, social organization, technology, and socioculturally produced symbolic structures.

Trends in Pleistocene and Early Holocene Biocultural Evolution

The ecological framework outlined in the previous section sets the stage for looking at the well-recognized and long-debated four prehistoric Near Eastern hallmarks noted in the introduction. This section aims to consider thoroughly the evolutionary issues that may be elucidated by applying the complex systems ecological perspective to the available paleoanthropological evidence associated with each hallmark.

Earliest Expansion of the Genus *Homo*: Out of Africa, into the Near East

Initial OOA expansion, primarily associated with the Lower Pleistocene – 2.60–0.78 mya – is well documented by in situ and surface Oldowan, Developed Oldowan, and Early Acheulean assemblages in the southern Levant (Figs. 3 and 4). Together, these sites fall into the Lower Paleolithic period. The sites are concentrated in the Mediterranean vegetation zone and the well-watered, very warm Jordan Valley-Dead Sea basin. At ca. 1.80 mya, the geologically oldest deposits likely associated with Lower Paleolithic artifacts are those of Erq al-Ahmar formation in the Jordan Valley. The best-known early localities – with stratified layers associated with lithic artifacts, faunal assemblages, and other archaeological traces – are 'Ubeidiya and Gesher Benot Ya'akov (Bar-Yosef 1998b; Goren-Inbar 2011). Long-term research at these sites documents geographic expansion in the genus *Homo*'s terrestrial, omnivorous, technologically dependent extractive niche. The exceptional preservation of botanical materials at Gesher Benot Ya'akov, dated to the Lower-Middle Pleistocene boundary, ca. 0.78 mya, is especially important. Associated with chipped stone artifacts and an animal bone assemblage, key food plant remains include edible underground storage organs (USOs), nuts, seeds, and fruits. Gesher Benot Ya'akov provides the best available archaeological evidence that, by the end of the Lower Pleistocene, human colonization of regions outside of Africa involved complex, socially coordinated and transmitted stone tool production practices, controlled use of fire, and a remarkably ecologically broad-spectrum pattern of omnivorous foraging with central-place consumption.

Even more than the Lower Pleistocene archaeological record in North Africa, the southern Levantine sites strongly – albeit indirectly – support the inference that early *Homo*, with evolutionary origins in sub-Saharan Africa, exploited Saharan green corridors and oases in the process of population growth and range expansion. Yet, the extreme rarity or absence of Lower Pleistocene archaeological sites in the northern Levant, Arabia, Mesopotamia, the Taurus-Zagros arc, and the Anatolian plateau suggests that hominin exploitation of patchy wetland corridors/oases or higher-altitude warm-season resources was limited, most likely occurring during relatively (geologically) ephemeral warm and humid climatic periods. Such periodic exploitation has been documented at Kaletepe Deresi 3 in central Turkey, dating to ca. 1 mya (Slimak et al. 2008). Successful Lower Pleistocene Eurasian range expansion may be clearly interpolated, not only by the rich record from Dmanisi but also by the establishment of substantial Lower Pleistocene hominin populations in eastern Asia and traces of Lower Pleistocene colonization in Western Europe. While future research will likely reveal more significant traces of Lower Pleistocene human settlement in Near Eastern subregions outside the southern Levant, the behavioral ecology of hunting and gathering predicts that population densities would have been very low where aridity or cold winter temperatures limited food or water availability and strongly raised the daily energetic costs of foraging. From a taphonomic perspective, we would expect archaeologically visible early sites to be very rare in the desert/steppe belt or at higher elevations. A further implication for Lower Pleistocene human evolution is that the initial

Near East (Including Anatolia): Geographic Description and General Chronology of the Paleolithic and Neolithic, Fig. 4 Examples of chipped stone tool types and technological features in Lower and early Middle Paleolithic technocomplexes in the Near East: 1, Oldowan chopper; 2, Acheulo-Yabrudian scraper; 3, Acheulean handaxe; 4, early Middle Paleolithic retouched Levallois blade; 5, Amudian facies (Acheulo-Yabrudian) naturally backed blade

expansion out of Africa may have involved recurrent local extinction and substantial chronological gaps in subregional occupation in much of the Near East.

Ecological Selective Pressures and Adaptive Evolution in the Lower Pleistocene The Lower Pleistocene would have been a (very long) period during which evolutionary selection pressures remained high for embodied socio-cognitive adaptations to reliably exploit diverse, dispersed, and often unpredictable plant and animal food resources. Such emergent adaptative phenotypes would likely have included increasingly complex linguistic information exchange; symbolic construction of self and other; ability to conceptualize narratives that enabled construction of memory, future planning, and decision-making; participation in larger, more stable long-term social networks; and coevolving life-history patterns of extended juvenile dependency periods and more intensive, cooperative parental transfer of resources to offspring. These adaptations in modern humans represent the evolutionary inheritance of long-term Pleistocene changes in brain ontogeny and anatomy, in the neuroendocrine system overall, and in growth and aging patterns across the life span. They now fit *Homo sapiens* to a globally distributed, ecologically dominant, and increasingly disruptive niche – one that is not only terrestrial, omnivorous, and extractive but also conspicuously socially intensive. Yet, there is very little clear evidence and, as a result, little scientific consensus about how these critical adaptations coevolved with the human niche in the Lower Pleistocene (and through the rest of the

Pleistocene, for that matter). What was the tempo and mode of their evolution? More specifically, to what extent was punctuated evolution involved in the spread of adaptive phenotypes, driven by recurrent speciation, range expansion, and competitive exclusion of one *Homo* population by another? Alternatively, to what extent did socio-cognitive and life-history adaptations evolve in a gradual pattern within a framework of multi-regional gene flow between sub-Saharan Africa and Eurasia, via the Near East?

The Tempo and Mode of Human Evolution in the Middle Pleistocene Two important trends are clear concerning hominin macroevolution in the subsequent Middle Pleistocene (ca. 0.78–0.13 mya; Fig. 3). The first is that sub-Saharan Africa remained a dominant source of population – and thus genetic variation – spreading via green corridors and oases across the Saharo-Arabian desert/steppe belt into Eurasia (Groucutt et al. 2015; Hublin et al. 2017). The second is that, whatever the nature of biological evolution in socio-cognitive and life-history adaptations during the Middle Pleistocene, the archaeological traces of human behavior indicate complex group-based omnivorous foraging – including hunting of prime adults from large ungulate prey species – along with social post-capture mobile-camp processing and consumption activity and complex group-based technological raw material provisioning and production patterns. In the Near East, recent exciting analyses have provided such evidence dating to the very end of the Lower Pleistocene at Gesher Benot Ya'akov, where researchers report the earliest well-documented instance of controlled use of campfires associated with omnivorous food remains and stone tools (Goren-Inbar 2011). Work at Qesem cave, dating to the mid-Middle Pleistocene, has yielded further contextual archaeological evidence for large game hunting and food sharing in a mobile camp setting (Stiner et al. 2011). Perhaps even more importantly, at least some of these social hunter-gatherer behaviors are documented within the arid/semiarid belt and higher-elevation zones – for instance, at the later Lower Paleolithic 'Ayoun Qedim site in the Jafr Basin, Jordan (Rech et al. 2007) – where year-round occupation would have been marginally productive compared to the southern Levant or the Taurus-Zagros foothills.

The Initial Spread of Modern Human Anatomy: Out of Africa, into the Near East

The initial OOA spread of modern human anatomy, across the Middle-Upper Pleistocene transition (ca. *130 kya, defining the boundary between marine isotope stages 6 and 5, together encompassing the span 170–80 kya*) is documented in the Near East most spectacularly by the mobile camp/burial sites of Skhul and Qafzeh caves, both located in the southern Levantine Mediterranean vegetation zone (Hovers 2009). Key Near Eastern sites that date to the end of the middle and beginning of the Upper Pleistocene are included in Fig. 3 (the site of Jebel Faya, with stratified early and mid-Upper Pleistocene archaeological components is shown in Fig. 5). The OOA expansion of anatomically modern humans is also indicated by recent comparative genetic analyses focusing on extant neutral variation in the Arabian Peninsula, further suggestively supported by archaeological work in southern Arabia (Groucutt and Petraglia 2012; see Fig. 5). Across North and sub-Saharan Africa, fossil finds dating more broadly to the 300–130 kya interval (the end of the Middle Pleistocene) provide the earliest evidence of modern craniofacial anatomical patterns (Hublin et al. 2017). However, the relatively abrupt appearance of two southern Levantine sites with multiple primary interment features – all dating to the interval ca. 130–90 kya, corresponding to the first millennia of the Upper Pleistocene – suggests a local cultural tradition of mortuary ritual in mainly *anatomically modern* mobile hunter-gatherer societies. The social networks, symbolic structures, and associated cosmologies that constituted and were constituted by the ritual practices cannot be reconstructed. Yet, the symbolically dramatic, ritualized response to the fundamental social crisis of death constitutes a hallmark human group-level behavior, which strongly shapes the surviving group members' comprehensive, shared memory and embodied

Near East (Including Anatolia): Geographic Description and General Chronology of the Paleolithic and Neolithic, Fig. 5 Selected late Middle Paleolithic (LMP) and early Upper Paleolithic (EUP) sites in the Near East: 1, Jebel Faya (EUP [with mid-Middle Paleolithic component]); 2, Shi'bat Dihya 1 (LMP); 3, Abu Noshra (EUP); 4, Tor Faraj (LMP); 5, Lagaman sites (EUP); 6, Nizzana XIII (EUP); 7, Boker Tachtit and Boker (EUP); 8, Tor Sadaf and Thalab al-Buhayra (EUP); 9, Erq el-Ahmar (LMP-EUP); 10, Mughr el-Hamamah (EUP); 11, Kebara Cave (LMP-EUP); 12, Tabun Cave (LMP) and el-Wad Cave (EUP); 13, Hayonim Cave (EUP); 14, Qafzeh Cave (EUP); 15, Amud Cave (LMP); 16, Manot Cave (EUP); 17, Ksar Akil Rockshelter (LMP-EUP); 18, Üçağızlı; 19, Karain Cave (LMP), Cave (EUP); 20, Dederiyeh Cave (LMP); 21, Wadi Kharar 16R (EUP); 22, Umm el-Tlel (LMP-EUP); 23, Shanidar Cave (LMP-EUP); 24, Zarzi Cave (EUP); 25, Hazar Merd Cave (LMP); 26, Warwasi Rockshelter (LMP-EUP); 27, Bisitun and Kobeh Caves (LMP); 28, Yafteh Cave (EUP). Base map source: Google Earth

sense(s) of identity in relation to others, to place, and to time. The repetitive nature of the ritualized interment of the dead at Qafzeh and Skhul caves points toward long-term cultural reproduction of social relationships, place, descent, and memory among mobile – indeed, quite likely very highly mobile – hunter-gatherer populations.

As important as this earliest evidence of mortuary ritual may be, the debate remains the same over how – in terms of macroevolutionary tempo and mode – the underlying socio-cognitive capacity evolved. Do we see a punctuated spread of anatomically modern human (AMH) populations that evolved in North and sub-Saharan Africa? Or do we see a more complex, gradual process of biocultural evolution, involving a multilevel social and biological interaction of local Near Eastern groups with sporadically expanding African groups, of groups in richer winter refugium habitats with groups in more marginal or patchier zones within the Near East, and of Near Eastern groups with neighboring South Asian, Central Asian, southern Caucasus, and European ones? Of course, the actual answer may be somewhere between the two theoretical extremes of punctuated speciation/replacement and biocultural gradualism.

The evidence for initial Upper Pleistocene Near Eastern AMH populations descending from late Middle Pleistocene African ancestors and constituting hunter-gatherer societies who practiced mortuary rituals may be especially

attention-grabbing. The Near Eastern data on emerging complexity in Upper Pleistocene human evolution becomes even more striking when one considers that all of the carefully excavated and radiometrically dated burials in the Near East from the subsequent period, ca. 80–50 kya, include individuals with predominantly Neandertal anatomical features (Bar-Yosef 1994). Radiometric analyses of animal teeth that may be stratigraphically associated with the Neandertal female adult burial from the Tabun Cave suggest that humans with Neandertal traits may have been in the southern Levant even earlier, contemporaneous with the anatomically modern humans interred at Skhul and Qafzeh (Grün and Stringer 2000). Uranium-thorium dating of calcitic crusts forming on an isolated anatomically modern human skull cap from Manot Cave most likely places the re-expansion of African or Saharo-Arabian populations beginning ca. 60–50 kya (Hershkovitz et al. 2015). In this critical period, it is currently unclear how the population-biological turnover – with anatomically modern humans largely replacing Neandertals – actually unfolded across the entirety of the Near East. However, new breakthroughs in genomic analyses of modern and ancient genomes alike suggest that Neandertal and anatomically modern human populations sporadically admixed over thousands of years, most likely in the Near East (Mallick et al. 2016). This is broadly consistent with the shifting morphological patterns of the Near Eastern human fossils themselves, across the Middle-Upper Pleistocene boundary.

It is important to remember that Neandertals were a western Eurasian network of populations that exhibited a suite of cranio-dental and post-cranial anatomical features tending to distinguish them, not only from African AMH but also from Asian and possible archaic African populations in the late Middle-Upper Pleistocene timeframe, from ca. 200 kya onward. Neandertals themselves may be assumed to have descended, for the most part, from western Eurasian populations established during earlier Lower or Middle Pleistocene expansions out of Africa. The African AMH morphological pattern incorporates a relatively high, rounded cranial vault, limited midfacial prognathism, strong basicranial flexion, chin formation, and a relatively narrow torso with non-cold-adapted brachial and crural indices (resulting in a higher encephalization quotient). The Neandertals, in contrast, tend to display strong midfacial prognathism associated with a straight or receding mandibular symphyseal region, a distinctive occipital morphology involving lambdoidal flattening, posterior "bunning," a wide suprainiac fossa, maximal cranial breadth in the supramastoid region, and small, medio-inferiorly oriented mastoid processes. Neandertal postcranial anatomy tends to be robust, combining cold-adapted torso shape and limb proportions with locomotive adaptations for high activity levels. Although Neandertal brains were as large or larger than those of AMH (fully in the modern human range), their higher body mass indices yield an encephalization level similar to that of Middle Pleistocene archaic *Homo*. At least for males – who are better represented among post-cranial remains – the Neandertal anatomical pattern is suggestive of high caloric intake and high energy flux. As a consequence, reconstructing Neandertal diet and behavior is vital for modeling possible differences with AMH in activity adaptations and their life-history consequences in terms of growth rates, growth-maturation trade-offs, adult maintenance-fertility trade-offs, and intergenerational resource transfer effects imposed by variation in adult longevity. The complete anatomical pattern is most often observed on European Neandertals dating to the Upper Pleistocene, in the period ca. 130–45 kya. This pattern is also observed on Neandertal skeletons from burials in Shanidar Cave, located in the Zagros foothills – set in a key Near Eastern winter refugium zone. The Shanidar burials have been dated by conventional radiocarbon assays on associated charcoal fragments, and although there is substantial uncertainty over such ages, the burials probably date to (very roughly) 50 kya (Solecki 1971).

It is emphasized that the Neandertal anatomical pattern fully emerges earliest in Western Europe, ca. 200–120 kya, and consequently, the appearance of Neandertal features in the Taurus-

Zagros foothills, the northern Levant, and the southern Levant between ca. 80 and 50 kya (and possibly earlier in marine isotope stage 5, ca. 130–80 kya) indicates that a trend of population expansion from Europe to the Near East interrupted the incipient spread of AMH populations out of Africa (Bar-Yosef 1994). Notably, skeletal specimens generally described as Neandertal from the southern Levant also show some features of the parietal or mastoid regions more commonly expressed in AMH (Kramer et al. 2001). Recent comprehensive reconstruction of ancient DNA extracted from European Neandertal bones indicates that all living non-Africans have inherited roughly 1–4% of their DNA from Neandertals – with most or all of the remainder from early AMH ancestors. The southern Levant – as perhaps the most important Near Eastern winter refugium zone, especially well linked to semiarid zone green corridors and oases – is the most obvious candidate area for Neandertal-AMH population mixture in the initial portion of the Upper Pleistocene. Yet, this only intensifies the debate over tempo and mode. Are we observing competition between biologically distinct populations, with limited hybridization? Or are we seeing a regional, shifting population balance – perhaps due to climate change or even cultural-technological innovation – in anatomical or life-history features favored by natural selection?

It should not be surprising that the (apparently predominantly anatomically) Neandertal societies who occupied the Near East in the mid-Upper Pleistocene interval, ca. 80–50 kya, appear to have been at least as socially complex and ecologically adaptive as the earlier AMH communities, especially when it came to mobile hunting and gathering in relatively marginal ecological zones, including both semiarid and higher-elevation habitats (Henry 2003). Given the behavioral similarities between AMH and Neandertal hunter-gatherer societies in the earlier Upper Pleistocene of the Near East, it becomes even that much more challenging to clarify the systemic causes for the observed, long-term geographic shifts in anatomical variation.

The Middle-Upper Paleolithic Transition, Disappearance of Neandertals, and Eurasian Spread of Anatomically Modern Humans

*The decisive expansion of Upper Paleolithic technology – significantly associated with modern human anatomy – in the later Upper Pleistocene (*ca. *50–20 kya)* marks the disappearance of the Neandertal anatomical pattern in the Near East (and the rest of western Eurasia). In fact, the spread of Upper Paleolithic technology and modern human anatomical features had global biocultural ripple effects. The expansion of early Upper Paleolithic populations across Eurasia strongly contributed to the predominantly sub-Saharan African pattern of genetic variation seen in all living humans. That is to say, the bulk of extant non-African neutral genetic variation is a subset of variation found in living sub-Saharan African populations (Mallick et al. 2016). During the Upper Paleolithic, major innovations involving refined fiber working, tailored clothing and rigid footwear, compound tool production (with replaceable flint tool or point inserts), projectile hunting weaponry, and body and clothing decoration become efficiently produced and widely employed for the first time outside of sub-Saharan Africa. While it is likely that Eurasian adoption (s) were sometimes the result of independent invention, it is at least as likely that the socio-demographic and ecological conditions favoring adoption of these key technological innovations developed later outside of Africa. These innovations facilitated more sustainable or successful long-term hunter-gatherer occupation of highly marginal Eurasian zones, including higher-altitude or higher-latitude areas with very long winters or very little rainfall, including interior Arabia and Mongolia. The development of Upper Paleolithic Eurasian societies – and the longer-range exchange networks that often shaped them – unfolded slowly, over a ca. 30,000-year period.

Upper Paleolithic emergence, with AMH re-expansion out of Africa, appears to have begun in the Near East before spreading into Eurasia. More specifically, available radiocarbon dating evidence indicates that the Upper Paleolithic emerged first in the Levant – and, quite

likely, was localized in the southern Levant, between 50 and 45 kya (Alex et al. 2017). Key late Middle Paleolithic and early Upper Paleolithic sites in the Near East are shown in Fig. 5. Between 45 and 40 kya, aspects of Upper Paleolithic material culture spread or were independently adopted across southeastern, central, and much of Western Europe (Bar-Yosef and Belfer-Cohen 2010; Kuhn and Zwyns 2014).

The very earliest Near Eastern Upper Paleolithic is archaeologically recognizable by specific changes in lithic technology. In fact, aside from shifts in blank production, flake-use, and retouched-tool production practices, the earliest Upper Paleolithic layers do not exhibit evidence for residential and mobile foraging behavior patterns that are dramatically – or at least, clearly archaeologically – different from those evidenced from underlying final Middle Paleolithic deposits. Moreover, artifacts and features that have been proposed as part of an Upper Paleolithic behavioral "revolution" are actually rare or absent in earliest Upper Paleolithic Near Eastern sites. These include decorative beads and pendants, bone tools and points, and formal burials, all of which gradually increase frequency after 45 kya, only later becoming substantially more common during the Epipaleolithic period, ca. <20 kya. The early Upper Paleolithic, at first, involves adopting new patterns or combinations of lithic technologies for mobile foraging and campsite tasks.

What is it that changed in the Near Eastern Middle-Upper Paleolithic transition? Terminal Middle Paleolithic assemblages exhibit few formal tools except for Levallois points. While some late Middle Paleolithic chipped stone assemblages indicate a tendency toward producing narrow elongated blanks, lithic reduction is dominated by the unidirectional convergent Levallois technique for producing broader points and flakes. In contrast, the oldest documented Upper Paleolithic assemblages are more clearly "leptolithic," or blade-focused, in core-reduction practices (Fig. 6). Moreover, formal retouched points and tools are much more diverse and abundant. They variably include relatively thick convergent points, narrow points on blades (el-Wad points), end scrapers, burins (often on truncations), scaled pieces, and retouched blades.

For the most part, the earliest Upper Paleolithic assemblages – that is, those dated to ca. 50–40 kya – are from sites in the Levant (see Fig. 5). They usually conform to one of two technological patterns, the Early Ahmarian and the Initial Upper Paleolithic. The Early Ahmarian technocomplex features prismatic blade and bladelet production, often on single-platform narrow- or broad-fronted cores, along with el-Wad points. According to the most recent, careful work on pretreating wood charcoal samples and measuring their ^{14}C levels, the oldest Early Ahmarian assemblages are from Kebara and Manot caves, near the Mediterranean coast in northern Israel; these occupations likely date to ca. 47–45 kya (Alex et al. 2017). The lithic assemblage from Mughr el-Hamamah includes Early Ahmarian prismatic blade(let) production technology and may be as old as 45 kya. The Initial Upper Paleolithic (IUP; often referred to as the Emiran in the southern Levant) involves a core-reduction strategy combining prismatic blade production on the lateral portions of the core, with the main prepared-core convexity utilized for Levallois elongated point production. Interestingly, at most sites with IUP assemblages, there are also stratigraphically younger Early Ahmarian deposits. However, the reverse sequence has not been documented. Currently, it appears that Early Ahmarian technologies were adopted immediately following the late Middle Paleolithic in Mediterranean vegetation zones in the southern Levant. In surrounding areas – including the Negev, southern Jordanian highlands, the mountainous Mediterranean coast from Lebanon to Turkey, and northern Syria – IUP technologies were first utilized, only subsequently giving way to Early Ahmarian ones. The oldest dated Upper Paleolithic assemblages from the Taurus-Zagros foothills are assigned to the Baradostian technocomplex; they appear to be somewhat younger in age (ca. 40–35 kya), exhibiting retouched blade and bladelet products similar to those from Early Ahmarian assemblages in the Levant. As a cautionary note, chronological details in different parts of the Near East remain uncertain. Across

Near East (Including Anatolia): Geographic Description and General Chronology of the Paleolithic and Neolithic, Fig. 6 Examples of chipped stone tool types and technological features from mid-Middle Paleolithic, late Middle Paleolithic, early Upper Paleolithic, and late Upper Paleolithic technocomplexes in the Near East. 1, mid-Middle Paleolithic radial Levallois core (lateral view); 2, late Middle Paleolithic Levallois point; 3, initial Upper Paleolithic/Emiran end scraper; 4, initial Upper Paleolithic/Emiran Ksar Akil point; 5, initial Upper Paleolithic/Emiran Levallois-like blade; 6, Levantine Aurignacian burin; Late Ahmarian Dufour bladelet; Early Ahmarian el-Wad point

the wider early Upper Paleolithic timeframe 50–30 kya, it may still be technically challenging to sample, pretreat, and date biogenic materials suitable for radiocarbon dating. This is especially the case when materials are poorly preserved or from old excavations with poorer control over depositional context. Thus, an important focus for future work is clarifying geographic variation within the Near East over the chronology of early Upper Paleolithic technological change in environmental and biocultural context.

Explaining the Middle-Upper Paleolithic Transition: A Socio-Technological Hypothesis Indeed, elucidating how and why socio-technological practices changed in this critical interval can clarify why anatomically modern humans largely replaced Neandertals across western Eurasia between ca. 50 and 30 kya. Kuhn and Stiner (2006) have presented theoretical arguments and tentative evidence to support a key inference. The elongated blanks, burins, end scrapers, and retouched blades that mark the earliest Upper Paleolithic assemblages in the Near East were part of an otherwise hidden – but profound – shift in social organization. The production of smaller flint tools and projectile points that were likely hafted – and often used for working hide, wood, or bone – likely marks an increased labor investment in technological production to

support hunting, gathering, and food processing. Thorough ethnographic comparison of hunter-gatherer social organization indicates that high labor investment in technological production tasks often corresponds to effective division of labor, usually along adult gender lines. Thus, Kuhn and Stiner identify a hallmark biocultural evolutionary development in the early Upper Paleolithic: the establishment of more stable social networks, constituted by more predictable co-residence practices and cooperative organization of labor.

This model has two important predictions that find preliminary empirical support. First, on an evolutionary, intergenerational timescale, increased division of labor should be an economic response to rising human population impact on those food resources which – other things being equal – offered higher calorie and nutrient returns under the prevailing late Middle Paleolithic socio-technological systems. During the interval ca. 65–50 kya, cooperative hunting practices focused around Levallois technology appear to have been sufficiently successful to depress wild cattle populations in the food web surrounding Kebara Cave, located near Mt. Carmel's southern tip. Among the largest herbivorous mammals in the Pleistocene Near East, wild cattle (*Bos primigenius*) provided foraging groups with especially rich post-capture nutrient returns. Yet, the late Middle Paleolithic archaeological sequence in Kebara Cave reveals that, from an early, relatively high focus on wild cattle (ca. 65 kya), identifiable *Bos* food remains decline in abundance, becoming uncommon in the uppermost Middle Paleolithic layers (Speth and Clark 2006). Across Near East sites, wild cattle never reach the relative-abundance peak; when compared to other hunting resources, they attain in the lowermost layers of Kebara Cave (Fig. 7). Speth and Clark argue that human hunters – likely Neandertal or admixed Neandertal-modern human populations, to judge by hominin skeletal remains from late Middle Paleolithic burials – had at least a local impact on *Bos* populations. Second, late Middle Paleolithic socio-technological systems appear to have been organizationally simpler, involving fewer task-specific technological products and greater mobility than those seen in later Upper Paleolithic ones; the time allocation trade-off between more flexible foraging and residential mobility, on the one hand, and more technological task activity, on the other, would marginally favor the lower body mass and less powerful masticatory biomechanics of anatomically modern humans, compared with Neandertals. In metabolic and dietary terms, the Upper Paleolithic pattern would have traded off greater daily energy flux – in which more calories would have been spent searching for higher caloric rewards involved in hunting – for lower variation in daily energy balance, which a marginal increase in plant foods would have provided. The demographic consequences of such a shift may have been small but substantial, leading to higher fertility, lower infant and juvenile mortality, and greater post-reproductive longevity.

It is important to note that the development of greater culturally structured division of task labor may have occurred substantially earlier in parts of sub-Saharan Africa. In any case, the shifts occurring in the earliest Upper Paleolithic in the Near East appear to have had long-term consequences. The social practices that shaped and reinforced division of labor would have been set within mobile camps, during moves between campsites, on raw material provisioning trips, and on foraging trips. Near Eastern Upper Paleolithic sites – when compared to deposits from earlier periods – appear to vary along a substantially greater spectrum of ephemeral, task-specific camps and larger, repeatedly occupied mobile base camps. Occupation of higher-elevation, semiarid, and arid zones gradually became more successful, complex, and resilient. By the onset of the Epipaleolithic (ca. 20 kya), a persistent social boundary in lithic style had crystallized between the Mediterranean zone and adjacent semiarid zones in the southern Levant (Stutz and Estabrook 2004). At the same time, the early Epipaleolithic record around the Azraq Basin, Jordan, indicates that this boundary was actively, dynamically negotiated (Richter et al. 2011). Early and middle Epipaleolithic (ca. 20–15 kya) basecamp sites that were repeatedly reoccupied exhibit some durable stone-foundation architectural structures and burials, especially in the southern Levantine Mediterranean zone.

Near East (Including Anatolia): Geographic Description and General Chronology of the Paleolithic and Neolithic, Fig. 7 Long-term dynamics in big game (as represented by aurochs, fallow deer, and mountain gazelle) and small game (as represented by spur-thighed tortoise) in southern Levantine Middle Paleolithic, Upper Paleolithic, and Epipaleolithic archaeofaunal assemblages, from ca. 200 kya to 12 kya. Big game evenness (left vertical axis) measures the dominance – or lack of it – among bones and bone fragments from large (mainly aurochs), medium (mainly fallow deer), and small (mainly gazelle) ungulate species. Because aurochs were relatively less frequently hunted by humans during the Pleistocene, evenness values approaching 1.0 during the late Middle Paleolithic reflect greater focus or success in hunting "the biggest of the big." Evenness values approaching 0.0 during the Early and Late Natufian cultural periods reflect the preponderance of gazelle bones in these late Epipaleolithic assemblages. Testudo abundance index (right vertical axis) refers to the number of identifiable spur-thighed tortoise (*Testudo graeca*) bones and bone fragments relative to the number of big game bones in the same assemblage. Taken together, the two archaeozoological measures suggest that as Middle Paleolithic foragers became more successful at hunting big game – more often taking larger-bodied species – human population grew slightly but significantly, generating predation pressure on smaller, easy-to-capture animal food resources. In the late Middle and Upper Paleolithic, as human population growth and ongoing hunting success depressed big game populations, foragers turned increasingly to a wider diversity of small animal and plant food resources. In the Early and Late Natufian periods (ca. 15–12 kya), the *Testudo* abundance index rose dramatically, as big game continued to shrink in economic and dietary importance. Big game evenness and *Testudo* abundance index values calculated from published data

Anatomically Modern Human (Re)Expansion in the Middle-Upper Paleolithic Transition Kuhn and Stiner's division-of-labor model is compelling because of its broad biocultural explanatory reach, although much work remains to evaluate its predictions in greater detail. Researchers have also long sought to trace the population-biological dimensions of the Middle-Upper Paleolithic transition, as it roughly coincides with a key episode of anatomically modern human expansion out of Africa or southern Arabia. Levantine lithic assemblages with IUP core-reduction technology also variably incorporate artifacts – such as Nubian cores, chamfered

pieces, Emireh points, and Umm el-Tlel points – that are made with seemingly arbitrary, stylistic preparation or final-shaping removals. As its name suggests, the Nubian core-reduction approach to producing convergent flakes is a Middle Stone Age African phenomenon. However, Nubian cores are known from Middle Paleolithic sites in the Arabian Peninsula and Negev Desert. Nubian cores are notably part of the lithic assemblage from Boker Tachtit Level 1, an IUP site in the Negev Desert (see Fig. 5). The Nubian core pattern – and its formal similarity to Near Eastern IUP core reduction – supports the tantalizing possibility that some earliest Upper Paleolithic technologies in the Near East were influenced by social interaction and demographic expansion from Africa (Goder-Goldberger et al. 2016). However, Early Ahmarian technology appears to be a local southern Levantine development, attributes of which subsequently spread – likely through a combination of demographic growth, dispersal, and social interaction – to other parts of western Eurasia. At this point, evidence remains limited that Near Eastern early Upper Paleolithic material culture was directly influenced by demographically expanding anatomically modern humans, migrating out of Africa, via the Nile Valley or Bab el-Mandeb.

The Long-Term Emergence of Domestication and Agriculture in the Near East

*The transition from the final Paleolithic to the Neolithic is often viewed through the lens of the transition to sedentism, agriculture, and village life, which emerged "full-blown" in the Pre-pottery Neolithic B period of the Near East (*ca. *10.5–8.25 kya).* Flannery's (1969) classic archaeologically focused discussion of long-term Near Eastern sociopolitical change – along with the ecological and economic foundations and consequences of that change – included a key suggestion. He argued that plant domestication and agricultural production, which developed in the early Holocene, unfolded at the end of a long-term economic shift from large wild animal resources to more abundant but smaller animal and plant food packages. Moreover, he pointed to then preliminary evidence that the trend toward "broad-spectrum foraging" began early in the Upper Paleolithic. Although the systemic causes of the Middle-Upper Paleolithic transition remain poorly understood, more recent research indicates that the Upper-Final Paleolithic shift toward smaller hunted and gathered food packages may have had incipient southern Levantine origins in the (Neandertal-dominated) late Middle Paleolithic, ca. 65–50 kya (Speth and Clark 2006). Put another way, over roughly the last 60,000 years of Near Eastern prehistory, large hunted game became less and less important as a caloric and nutritional resource. At the same time, smaller animal and plant "resource packages" that are resilient to overharvesting became more central to the human diet. This background to the Near Eastern origins of agriculture is important because it involves what appears to be a continuous long-term trend (see Fig. 7).

How Did Plant and Animal Resource Consumption Change in the Long-Term Transition to Agriculture? The Upper Paleolithic and early Epipaleolithic use of food resources appears to change subtly and gradually from ca. 40–15 kya, with some fluctuations forced in part by climate change. As for the later Middle Paleolithic, small- and medium-sized ungulates – such as fallow deer, gazelle, wild boar, and wild sheep and goat – comprise the bulk of big game assemblages from across the Near East. Small game tends to be dominated by easy-to-capture terrestrial animals, especially land tortoises (see Fig. 7). However, when measured by species presence alone, small game assemblages are often diverse, including small mammals (often hare), waterfowl, and other game birds. Some riverine, lacustrine, and even marine coastal fish and shellfish are documented in the archaeozoological record. The late Upper Paleolithic site Ohalo II, Israel (ca. 23–22 kya), and the early Epipaleolithic site of Kharaneh IV, Jordan (ca. 19–18 kya), preserve especially rich charred plant food assemblages. Ohalo II provides evidence for a broad spectrum of wild fruit, nut, grain, and tuber resources (Kislev et al. 1992). It is worth noting that recent phytolith extraction and identification research on late Middle Paleolithic deposits in the southern

Levant also indicates human (likely Neandertal) exploitation of fruit, nut, and grass (presumably including starchy seed) food resources (Henry 2003). The late Middle Paleolithic phytolith evidence is supported by the rare, exceptionally well-preserved charred botanical sample from the Middle Paleolithic layers of Kebara Cave, revealing that Neandertal foragers regularly gathered wild pulses, among other food plants. These emerging – albeit still limited – results on Upper Pleistocene Near Eastern plant food exploitation may be combined with archaeozoological research to suggest that the long-term shift toward smaller-package-sized food resources initially developed continuously and slowly, probably across the Middle-Upper Paleolithic transition.

Recent research on the Epipaleolithic in Jordan has been important for shedding light on how climatic and ecological gradients (see Fig. 1) may have shaped long-term biocultural change in the Near Eastern transition to agriculture. It appears that, as overall population densities grew to a critical threshold, hunter-gatherer groups more regularly sustained exploitation of wetland patches, which dotted the steppic or semiarid eastern flank of the southern Levant. In Eastern Jordan, the number and maximum size of archaeological sites jump substantially from the late Upper Paleolithic to the early Epipaleolithic. This transition unfolds during the Last Glacial Maximum (LGM), ca. 23–19 kya. This was a period of cold, dry climate globally. In the Near East, the cooler prevailing temperatures depressed annual precipitation rates, but they also reduced evaporation. The result was patchy change in water availability and vegetation regimes. In the southern Levant, the Lake Lisan that filled the Jordan Valley shrank progressively during the LGM. However, wetlands and upland lakes continued to dot the Transjordanian highlands and portions of Eastern Jordan. These were areas that – due to their higher elevation and relatively lower rainfall – supported lower annual biomass production than much of the western portion of the southern Levant. Thus, they would have had lower, spatially patchier amounts of edible plant and animal foods for human foragers. Still, predictable lacustrine and wetland zones – such as the ancient Lake Hasa and the wider Azraq region – were more intensely exploited by mobile foragers. At least occasionally, hunter-gatherers may have visited or remained in these areas throughout the year, especially the rich Azraq Basin (Richter et al. 2013). Substantial variation in bladelet and point manufacture and form suggests that material culture style was important in negotiating social relationship networks and boundaries. However, the very long-term trend in animal prey overexploitation – seen in the richer Galilee, Mt. Carmel, and Jordan Valley zones – does not develop around the ancient Lake Hasa or Azraq Basin, even into the early Holocene (Martin et al. 2016; Munro et al. 2016; Stutz et al. 2009). It is likely that the costs – in terms of foraging risks and residential-move distances – limited human ecological impact on the eastern portion of the Levant. At the same time, the Mediterranean vegetation zone and rich Jordan Valley remained a hunting-and-gathering refugium. Within this area, dotted by multiple biodiversity hotspots, human population densities gradually rose over millennial timescales. The higher rates of social interaction in co-residential, foraging, mobility, and ritual-gathering contexts had to be negotiated, influencing biocultural change in ways that have yet to be fully understood. An interesting focus for future research is how interaction between ecologically more productive lower-elevation refugia – including portions of the southern Levant and the Taurus-Zagros foothills – and patchier wetland oases in steppic and semiarid zones dynamically shaped both population growth within the Near East and demographic expansion into surrounding areas.

Such tension – between how forager social networks dwelled in the ecologically richer and wetter western Mediterranean and Jordan Valley zones and how they exploited the ecologically patchier grassland areas to the east and south – appears to have been involved with a major, punctuated prehistoric change occurring around 15 kya. At this time, the Early Natufian archaeological culture emerged, with several larger semisedentary or sedentary hamlets (ca. 1000–2000 m^2 in area) established in the Mt. Carmel,

Galilee, and Jordan Valley areas of the southern Levant. The successive Early and Late Natufian archaeological cultures (ca. 15–13 and 13–12 kya, respectively) involved substantial change in the scale and organization of settlement and food exploitation, mainly in the Levant. Figure 8 shows the distribution of Early and Late Natufian sites in the Near East. As many sites incorporate burial features, the Natufian archaeological culture also marks a shift in how regularly mortuary ritual produced social memory, a sense of place and of kinship descent within habitation loci. There is indirect evidence for Early Natufian Mediterranean zone population densities having risen, compared to earlier periods. In the Mt. Carmel and Galilee area of the southern Levant, Early Natufian archaeofaunal samples show a striking drop in the relative proportions of fallow deer bone fragments, when compared to immediately preceding Epipaleolithic periods. Gazelle bones dramatically come to dominate the big game fraction. In other words, considering that adult gazelles have roughly 1/3 to 1/5 the body mass of adult fallow deer, Early Natufian big game food resources include mainly "small big game" (Stutz et al. 2009). In fact, for the first time in the Pleistocene sequence of anthropogenic big game bone assemblages in the Near East, Early Natufian samples incorporate a large fraction of remains from very young, incompletely grown juvenile

Near East (Including Anatolia): Geographic Description and General Chronology of the Paleolithic and Neolithic, Fig. 8 Early Natufian sites (red markers) and Late Natufian sites (green markers) in the Near East. Orange markers show southern Levantine sites with stratified Early Natufian and Late/Final Natufian components. Green dashed line shows approximate current boundary between Mediterranean vegetation and Irano-Turanian steppe/grassland vegetation. Base map source: user Fulvio314 on http://it.wikipedia.org

Near East (Including Anatolia): Geographic Description and General Chronology of the Paleolithic and Neolithic, Fig. 9 The gazelle predation pressure index is the proportion of unfused first phalanges among all gazelle phalanges in Middle Paleolithic, Upper Paleolithic, and Epipaleolithic archaeofaunal assemblages in the southern Levant, ca. 200–12 kya. The mountain gazelle (*Gazella gazella*) first phalanx fuses around ca. 6 months of age, well before the juvenile has reached adult size. Thus, the substantial jump in juvenile gazelle proportions seen for the Early and Late Natufian periods signals a drop in the caloric and nutritional value of the typical big game catch while also further contributing to big game population depression. The index is calculated from published data

gazelles (Fig. 9). Moreover, Early Natufian small game assemblages exhibit a sudden shift – when compared to earlier Epipaleolithic or Upper Paleolithic samples – to a dominance of sessile animals, mainly hare and partridge (Stutz et al. 2009). After ca. 15 kya, hunter-gatherer populations were having an ecological impact on economically key prey species in the food webs set in Mediterranean and Jordan Valley refugium zones (Stiner and Munro 2002; Stutz et al. 2009).

Paleobotanical remains are generally poorly preserved in Early Natufian sites. It is unclear if there was an equally dramatic shift in the composition of the Early Natufian plant food spectrum. Preservation of charred botanical remains has proven poor at southern Levantine Early Natufian sites, but phytolith analysis suggests that forest resources, such as acorns, were gathered and utilized (Rosen and Rivera-Collazo 2012). Nutritional and caloric arguments would predict that rich, seasonally available foods that could be mass-collected and stored would be favored. Such resources in the final Pleistocene of the southern Levant would notably include acorns, wild pulses, wheat, and barley. The focus on fast-reproducing, fast-escaping small game – now very well documented by Stiner and Munro's (2002) pioneering analyses – provides an economic context that would also be congruent with mass collection of ecologically abundant starchy, fatty, or protein-rich plant foods. Both fast-reproducing small game and rich plant foods require high up-front technological investment for humans to harvest, transport, and process them sufficiently effectively. As the work by Stiner and Munro indicates, sessile small game would likely have been captured during Early Natufian times with complicated technological aids. These would include traps (which would not have to be constantly monitored), bow and arrow or harpoon technologies, and tracking or hunting dogs. All of these innovations would have substantially increased post-encounter return rates. If well curated, the initial investment in such technology would have paid off over weeks, months, or years of use. Perhaps most importantly, such small game species would be relatively undisturbed by human presence; their

high reproductive rates could offset intensive human predation. Thus, even as Early Natufian hunter-gatherers ate more hare, partridge, waterfowl, fish, and other sessile animals, encounter rates would unlikely have been depressed. It is important to note that the technological investment in sickles, baskets, mortars and pestles, and – possibly – storage pits for high-quality seed, nut, and lentil exploitation involves a conspicuously similar up-front cost and delayed returns, when compared to intensive sessile small game hunting.

Yet, there are two potential differences with seed, lentil, and nut exploitation. First, efficient harvesting and processing may be enhanced, not only by technology but also by social organization. Economies of scale, leadership, and task-specific division of labor can improve harvest rates, plant regeneration rates, and the effectiveness of storage and food processing. Whereas the adoption of small game hunting technology would mainly involve intensification of existing Upper Paleolithic hunter-gatherer social relations, the biological and physical properties of especially rich seed and nut resources can focus common interests and favor cultural transformation toward a larger scale of work organization, shaping seasonal ritualized aggregations or feasts. Moreover, an economy of scale supported by more complex organization could enhance plant habitat and dispersal, creating further ecological conditions for increasing caloric and nutritional return rates. Second, the biological and physical properties of starchy or fatty plant foods can – with efficient technology and organization of grinding and cooking – be used to produce relatively energy-rich gruels or porridges that can significantly augment lactation and reduce weaning ages, thereby increasing overall fertility rates in the community.

Over a period of generations, then, systemic change would most likely involve dynamic feedbacks among plant resource growth and patch distribution; technology supporting and facilitating harvesting, food processing, and storage; ritualization, genres of discourse, identities, built environments, cultural landscapes and temporalities, and cosmological idealization of a social order; practical social organization of plant food exploitation, along with social negotiation over task group mobilization, especially in the face of resource scheduling conflicts and the need to reach consensus about opportunity costs; practices of exchange, storage, and consumption; population fertility, mortality, health, and activity patterns; and migration, social boundary negotiation, and intermarriage practices.

It is not until the succeeding Late Natufian archaeological culture (ca. 13–12 kya) that we see evidence for a further, clear increase in the economic importance of rich, starchy plant foods. The site of Tell Abu Hureyra in the northern Levant shows that, for one thing, the Late Natufian archaeological culture – which stratigraphically succeeds the Early Natufian at several sites in the southern Levant – involved intense gathering and processing of wild plant foods in the Middle Euphrates valley. Late Natufian sites are geographically widespread, also found in the Eastern Jordanian Black Desert, the Negev Desert, and the Sinai Peninsula (see Fig. 8). Analysis of the charred macrobotanical remains from Abu Hureyra shows that, at the very beginning of the Late Natufian archaeological culture (Abu Hureyra 1, Phase 1), a year-round basecamp settlement was supported by a starchy plant-food foraging "basket" strongly dominated by wild wheat and rye. The technology and organization of seed resource exploitation practiced by the inhabitants of Abu Hureyra appear to have been resilient to rapid-onset climate change, which occurred during the cold and dry Younger Dryas episode (12.9–11.7 kya). Gordon Hillman (reporting in Moore et al. 2000) documents a Younger Dryas-associated shift toward a much broader spectrum of wild seeds, nuts, and fruits, available from a wider diversity of habitat zones, during the Abu Hureyra Phase 2 and 3 occupations. Similar Younger Dryas patterns of broad-spectrum seed and lentil exploitation have been documented at other late Epipaleolithic sites in the northern Levant and eastern Anatolia. These include Mureybet and Hallan Çemi. In the southern Levant, although Late Natufian sites also lack good macrobotanical preservation,

evidence for the increasing dietary importance of starchy seed resources comes mainly from phytolith evidence (Rosen and Rivera-Collazo 2012). It also comes from an indirect – but compelling – source. The Early-Late Natufian transition across the Levant, ca. 13 kya, is archaeologically marked, in part, by a shift from deep groundstone mortars in the Early Natufian to flat, more portable groundstone slabs in the Late Natufian phase. Dubreuil's (2004) microwear analysis comparing Early Natufian deep mortars with Late Natufian grinding slabs indicates that the former were used to crush and grind multiple food and pigment resources, whereas the latter functioned primarily to process starchy grains. It is notable that small sessile game comprises a smaller proportion of the animal bones from most Late Natufian sites, when compared to the EN pattern of small-sessile-game dominance. At the same time, Late Natufian big game assemblages remain overwhelmingly defined by gazelle remains (i.e., the smallest body-size category of big game available in regional ecosystems), and 35–40% of those gazelle bones are represented by even smaller, pre-reproductive subadult animals (Stutz et al. 2009). Gazelle populations under predation by humans appear to have been intensively targeted throughout the Early and Late Natufian cultural phases, but small fast game became less economically important in the Late Natufian. While recovery and analysis of plant food remains must be an important focus for future Epipaleolithic research in the Near East, there is a strong circumstantial case that starchy seeds – including wild precursors to many domesticated grains and pulses – supplied an increasing proportion of the per capita calories consumed in Late Natufian societies.

The Early and Late Natufian archaeological cultures provide evidence that wild plant resources increased – in successive steps over more than three millennia – in nutritional, energetic, and cultural importance for Near Eastern human populations. Experimental harvesting work suggests that the Late Natufian cultural phase likely involved small-scale predomestication cultivation activities. The succeeding Prepottery Neolithic A period (ca. 12.0 kya – 10.5 kya) has yielded indications that – at the very end of the Younger Dryas or the beginning of the Holocene – domesticated grains and lentils began to be planted, harvested, and consumed. However, this early agricultural production was mixed with a broad spectrum of gathered seeds, nuts, fruits, and lentils (Asouti and Fuller 2013; Willcox 2007). Wild big and small game continued to be hunted. During the Prepottery Neolithic B period (ca. 10.5–8.2 kya), wheat agriculture became the dominant plant-food-producing technology across the Near East, and sheep and goat domestication also spread quickly throughout the entire region. It was during the PPNB period – with the settlement of villages organized in uncut stone or mudbrick house blocks – that the "Neolithic Revolution" in the Near East took hold, sending out population and cultural ripple effects across much of Eurasia and into Africa.

Sociocultural and Environmental Implications of the Long-Term Transition to Agriculture The previous section presented an overview of how the omnivorous food resource base changed over a long but critical timeframe in Near Eastern prehistory – from the early Upper Paleolithic to the Prepottery Neolithic B period (ca. 50 kya – 8.2 kya). Sherratt (2007) has directly compared the agricultural technology underlying the shift to a carbohydrate-intensive plant-based diet to modern industrialization's extraction, transportation, and communication technologies – the adoption and development of which drove and were in turn sustained by fossil fuel extraction. The so-called Neolithic Revolution – which, to be sure, unfolded gradually over many generations – came to impact dramatically how energy flowed between ecosystems and the human populations that recurrently engineered and impacted them. The early adoption of agriculture, domestication, and more widespread food storage in the PPNB period substantially raised local ecological carrying capacities, sustaining higher annual rates of energy and nutrient extraction for human groups. Yet, agriculture also created the

complex potential for systemic environmental, demographic, and cultural disruption and transition, over time and at multiple geographic scales.

The Near East's later Upper Pleistocene and early Holocene archaeological record traces a very gradual long-term average decline in the nutritional and energetic importance of big game, followed by a series of stepwise increases in the importance of energy-rich plant foods. This transition in the human omnivorous relationship to surrounding food webs tilted toward plant resources across the Early Natufian, Late Natufian, Prepottery Neolithic A, and Prepottery Neolithic B phases. Archaeological evidence also provides information about associated behavioral changes, involving raw material provisioning; tool production and use; hunting, gathering, food processing, and consumption; combustion technology for cooking, warmth, and other activities; residential mobility and social organization; and, for later time periods, animal domestication and the building, use, maintenance, and abandonment of complicated architectural structures – including monumental features – along with mortuary and other community rituals, social identity production, social boundary maintenance, and exchange and long-distance social networks (Asouti and Fuller 2013).

It is with Early Natufian emergence that we observe a departure from the Upper Paleolithic and earlier Epipaleolithic trend of long-term gradual behavioral change. The Early Natufian archaeological culture (ca. 15–13 kya) is associated not only with a seemingly quantum shift in food economy; it also involved the settlement of large (ca. 1000–2000 m^2), likely continuously occupied sedentary hamlets, with durable subcircular architectural structures and mortuary features located under, inside of, and between structures. The behavioral changes surrounding Early Natufian foraging and food consumption appear to have involved mainly intensification of earlier Epipaleolithic and Upper Paleolithic labor and social relationship patterns. In contrast, the Early Natufian shift in settlement – with greater social and physical investment in spatially dense, long-lasting shelters, food preparation areas, and communal spaces that were often marked by mortuary features – would have integrally involved a reconfiguration of social relationships, cultural mechanisms for resolving conflicts, and cultural ideas and experiences of social time, landscape, and memory.

Sedentary settlement in the Early Natufian archaeological culture was a response – in no small part, initially, at least – to long-term predation pressure on big game (Stutz et al. 2009). Larger prey – such as gazelle, wild goat, or fallow deer – appear to have become overhunted, demographically depressed, and more costly to search for. This would have been the result of long-term positive feedback between hunting success and population growth, unfolding slowly, at centennial or millennial timescales. Consequently, the sedentary foraging of smaller, easy-to-find, but costly-to-process plant and small game foods became more economical. The alternative would have involved paying the metabolic, social, and foraging opportunity cost of increasing the length and frequency of moves between mobile camps. The social and cultural implications of sedentary settlement, though, were likely transformative. Early Natufian sedentism may have been sustained by intensive hunting and gathering, but Early Natufian cultural structures for managing social life – within and between families, camps, and perhaps descent groups – may have been integral to negotiating the changing system of social relationships in the subsequent Late Natufian (ca. 13–12 kya) food economy, as starchy seeds, nuts, and lentils took on increasing energetic and nutritional importance.

Indeed, the conspicuous increases in the complexity of settlement organization and ritual practice that developed gradually – throughout the Near East, from the Late Natufian phase through the Prepottery Neolithic A (ca. 11.7–10.5 kya) and B/C (10.5–8.2 kya) periods – may be understood as a complex, recurrent process of social negotiation and reorganization at multiple population scales. With the Prepottery Neolithic A development of monumental architecture – including the tower and wall at Jericho and the extraordinary structures and relief carvings at Göbekli Tepe (Fig. 10; Schmidt 2010) – we see the emergence of a clear early Holocene trend, one

Near East (Including Anatolia): Geographic Description and General Chronology of the Paleolithic and Neolithic, Fig. 10 Enclosures C (foreground), D (rear-right), B (rear center), and A (rear-left) at the PPNA-PPNB site of Göbekli Tepe in southeastern Anatolia. The round enclosures are associated with Layer III at the site, which is dated to the Prepottery Neolithic A (PPNA) or very onset of the PPNB (ca. 11.5–10.5 kya). Further details are given in Schmidt (2010). The stone sculpture and reliefs on the limestone stelae that dominate the Göbekli Tepe enclosures – but that are also found in the nearby PPNA village site of Nevali Çori – are evidence suggesting that the transition to agriculture and village life integrally involved extraordinary social, worldview, and ideological change among early Neolithic communities throughout the Near East. Photo credit: Wikimedia Commons

that continues through the Prepottery Neolithic B with the construction and settlement of the first large villages. The built environment and community ritual increasingly structured social relationships and experiences, mediated by the ideological dimensions of monuments, dwelling, landscape, and the symbolic constitution of culture and nature. The prehistoric biocultural dynamics spanning the Early and Late Natufian phases through the Neolithic Revolution involved material manifestations of the social negotiation of worldview and community order.

Discussion and Conclusions: From Intercontinental Connections to Globalization

In this essay it is suggested that a geographically grounded approach – involving a consideration of biocultural dynamics at multiple spatial scales – gives a more thorough appreciation of the systemic causes and implications of long-term human population growth, range expansion, and the emergence of sociocultural complexity. This theoretical foundation helps us to clarify why major debates about the Near East's role in human prehistory still deal with classic evolutionary questions of tempo and mode. Have the interactions among genetic variation, ecological setting, demography, and culture emerged gradually throughout the Pleistocene? Alternatively, has it been mainly shaped by punctuated evolution – involving speciation, mainly in sub-Saharan Africa, range expansion, and competitive exclusion within and outside of Africa? Yet, the Near East is all the more important when one further considers the later prehistoric emergence of Upper Paleolithic social networks, Epipaleolithic sedentary settlements, and Neolithic animal and plant domestication and village life. This latter development moves theoretical attention away from macroevolutionary tempo and mode toward complex biocultural dynamics within anatomically modern *Homo sapiens*.

Indeed, the long-term Upper Paleolithic shift to smaller animal and plant food-resource "packages" preceded and shaped the so-called Neolithic Revolution in the Near East. This development

further contributed to a supracontinental transition. Viewed from a Paleolithic vantage point – which highlights the role of OOA population dynamics – the Neolithic is a turning point in human prehistory. No longer is Africa the geographic driver of major biocultural change on a supracontinental scale. Neolithic and agricultural emergence is mainly an endogenous biocultural development within the Near East. Here, population expansion, sociocultural interaction, and technological diffusion catalyze the spread of agriculture into much of Asia, Europe, and – indeed – Africa. From the ecological complex systems perspective emphasized in this essay, four general questions can crystallize ongoing research on the Upper Paleolithic, Epipaleolithic, and Prepottery Neolithic in the Near East:

- What were the systemic interactions among social networks, cultural symbolic structures (including landscape and the anthropogenic built environment), human agency, human demography, and the demography and (perhaps anthropogenically altered) habitat of plant and animal food resources?
- How did behavioral, symbolic, and food-web changes impact human genetic variation – by influencing patterns of random and culturally structured drift, gene flow, and natural selection?
- How did hemispheric or global climate change affect the timing and dynamics of major biocultural trends, such as the initial shift to sedentary settlement or the widespread adoption of grain agriculture?
- How did social interactions, migration, and interbreeding between populations in adjacent phytogeographic zones and subregions within the highly environmentally diverse Near East shape the long-term late Pleistocene-early Holocene biocultural change – especially as technological developments of textile and basketry production, tailored clothing, durable shelter, trapping and hunting projectiles, dog domestication, food storage, and agriculture dramatically altered food calorie production, energy balance, and stress across the entire region?

Clearly, these critical questions deal with intricate complex systems dynamics. And so far, research on Near Eastern Neolithic emergence has largely contributed to clarifying the questions themselves. Much inquiry remains to provide satisfying scientific answers.

The Near Eastern transition to agriculture is key for understanding a pivotal biocultural development in very long-term Upper Pleistocene-early Holocene shift from a core-periphery structure to a truly global Holocene pattern of population distribution. The study of Near Eastern prehistory highlights humanity's shared, predominantly African late Middle and Upper Pleistocene ancestry. It also has the potential to elucidate the intricate prehistoric underpinnings of Holocene developments as varied as prehistoric sociopolitical complexity and inequality, recent processes of gene-culture interaction, language and cultural diversification, and the historical development of world-systems political economy. Amplifying a suggestion made by Bar-Yosef (1998a) – concerning how insights from studying the transition to agriculture could illuminate the Middle-Upper Paleolithic transition in the Near East – this essay points toward a similar but broader approach. If the systemic and dynamic climatic, ecological, biological, demographic, and socio-symbolic factors involved in the largely endogenous Near Eastern agricultural transition can be clarified, perhaps paleoanthropologists can utilize such insights into biocultural evolution, in order to trace more intricately the human dimensions of earlier, recurrent Pleistocene OAA population expansions into Eurasia – which unfolded via the Near East.

Near East (Including Anatolia): Origins and Development of Agriculture

George Willcox
Centre National de la Recherche Scientifique, Berrias, France

Introduction

It is only during the last 10,000 years that *Homo sapiens* adopted a production economy based on cultivation of a selection of plants. Our species evolved as hunter-gatherers for more than 90% of its history. In many regions around the world, plants were taken into cultivation during the early Holocene. The cultivation of wild plants created new conditions in which selective pressures led to morphological domestication and production economies. Estimates of the number of regions worldwide where hunter-gatherer societies adopted cultivation have increased as researchers discover more of these. A conservative estimate would be 11, while some scholars would suggest over 20. A production economy permitted higher densities of population. The social consequences of this change in subsistence economy vary widely from region to region. In the Near East, the establishment of mixed farming based on wheat, barley, pulses, and herding of sheep, goat, cattle, and pigs was particularly productive and as a result spread rapidly to Europe and Central Asia. It fueled the civilizations of Mesopotamia, Egypt, Greece, and Rome. European colonialists introduced these species into many parts of the world.

The Near East is characterized by high biodiversity, in particular hundreds of species of

Near East (Including Anatolia): Origins and Development of Agriculture, Fig. 1 Present-day natural distributions of wild wheats and barley (einkorn populations in southern Syria are not shown). Past distributions were possibly different, single-grained einkorn has expanded into secondary habitats, and einkorn may have had a more southerly distribution during favorable climatic conditions

wild annual pulses and grasses. Environmental degradation over the last 10,000 years caused by overgrazing, agriculture, and deforestation masks the fact that this area at the end of the Pleistocene and beginning of the Holocene was rich in wild game, fruits, nuts, and seeds. The variation in vegetation and climate over short distances, for example, Mediterranean forests with 400 mm of rain give way to open steppe with less than 150 mm in less than 50 km, meant that a wide variety of food resources were available near the sites. This diversity and abundance provided circumstances favorable for the development of agriculture. Figure 1 shows the present-day natural distribution of wild wheats and barley, which grow in an arc that sweeps from the Zagros foothills west to the Taurus and then down a narrow strip parallel with the Levantine coast. This arc, which lies between the arid interior steppe and the more humid (and in the past more wooded) hillsides, is often referred to as the Fertile Crescent.

Definition

Agriculture implies *cultivation*, which may be defined as encouraging plants to propagate. This definition would include practices of hunter-gatherer populations in the recent past which, although having little contact with farmers, encouraged the propagation of wild plants that they gathered in order to avoid over-exploitation. This may indeed have been the case for Paleolithic foragers. Cultivation was not invented, but was the result of humans mimicking what they observed in nature. This might explain why agriculture arose independently in different areas of the globe. However, incipient cultivation of this kind has not been identified on archaeological sites. In the Near East the earliest cultivation so far recognized is *pre-domestic cultivation*, defined as the cultivation of morphologically wild plants. This is a prerequisite phase which led to morphological *domestication*, defined by specialists as a genetic change caused by selective pressures brought about by cultivation. In the case of Near East grain crops, most authorities agree that initial domestication involved unconscious or natural selection as opposed to conscious selection. This resulted in populations better adapted to cultivation. Morphological domestication can in some cases be identified from charred remains. *Agriculture* is an established production economy in which farmers depend for their subsistence on cultivation and, in many instances, herding. *Wild progenitors* are the living survivors of species that were taken into cultivation and domesticated.

The terms *PPNA and PPNB* were coined by Kathleen Kenyon for the Pre-Pottery Neolithic

levels at Jericho. These terms have remained in use simply as chronological demarcations and are used for the northern and southern Levant.

Historical Background

Interest in the origins of agriculture and domestic plants dates back to the nineteenth century, that of Darwin being a prime example, but in the Near East concrete archaeological data was extremely limited until the second half of the twentieth century. In the 1950s, three sites produced identifiable charred remains which could be dated by radiocarbon: Jericho located near the Jordan Valley in the West Bank, excavated by Kathleen Kenyon, Beidha in southern Jordan excavated by Diana Kirkbride, and Jarmo located in northern Iraq in the foothills of the Zagros Mountains, excavated by Robert Braidwood. Maria Hopf and Hans Helbaek (1959) were pioneering archaeobotanists at this time. For several decades these sites were key examples of early-agriculture villages. From the 1960s onwards more and more sites were discovered. The year 1969 brought the seminal publication *The Domestication and Exploitation of Plants and Animals* (Ucko and Dimbleby 1969) with ground-breaking papers by David Harris, Daniel Zohary, Kent Flannery, Willem van Zeist, and Jane Renfrew. In the 1970s, Willem van Zeist established sound methods of identification and sampling, while Gordon Hillman developed interpretive tools for the discipline. They worked on charred material from Mureybet and Abu Hureyra, key sites located in northern Syria. Meanwhile, agronomist Jack Harlan and geneticist Daniel Zohary were investigating plant domestication from a biological point of view and examining wild ancestors in their natural habitats. Their research led to a better understanding of the processes involved in domestication and continued for many years (Harlan 1995; Zohary et al. 2012).

Archaeologists have much debated the theoretical explanations for the origins of agriculture. One of the first was Gordon Childe, who in the 1920s, developed the concept of the Neolithic Revolution. Today the consequences of adopting agriculture are seen as revolutionary, rather than the process. Hypotheses abounded in the second half of the twentieth century. In 1953 D. Clarke developed an ecological model, L. Binford's 1969 model was demographic, and K. Flannery in 1969 produced a model based on the broad spectrum revolution. In the 1990s O. Bar-Yosef among others suggested that climate change was a prime factor for the origins of agriculture. These models were based on environmental determinism. Sociocultural models were developed by Jacques Cauvin (2000) who saw religion as a key factor, while for Trevor Watkins, social complexity and the concept of the house as home were contributing factors.

Between 1995 and 2013 there has been a tremendous increase in the number of sites and the quantity and quality of analyzed plant remains. This has resulted in a body of information which provides a complex chronological and geographical picture and a mosaic of different cultural and environmental zones. Clearly no simple explanation for the adoption of cultivation would be applicable to the whole region.

Late Upper Paleolithic Foragers

Detailed evidence for late Upper Paleolithic subsistence comes from a single site, Ohalo II dated to 23,000 BP (Weiss et al. 2008) (for Cultural Periods, see Table 1). Situated on the shore of the Sea of Galilee in present-day northern Israel, Ohalo II became waterlogged, which provided exceptional conditions of preservation (see Fig. 2 for dates and locations of the sites mentioned). Several brush huts were excavated which contained thousands of seeds including grasses and cereals, notably wild emmer and wild barley. A large quern was found in one hut, associated with charred cereal grains and presumably used for grinding grain. This exceptional site provides evidence that subsistence was based on a broad spectrum of plant and animal species. However, comparisons with other sites are problematic because sites of this period are rare. It is probable that this broad spectrum subsistence, based partly on cereals, was more generalized in the southern

Near East (Including Anatolia): Origins and Development of Agriculture, Table 1 A summary of plant subsistence, cultural periods, and dates. Not all scholars agree on the dates for these periods. Rather than giving a range of dates for the beginning and the end, dates here have been rounded off

Subsistance	Cultural period	Dates BP cal.
Expansion of farming outside of the Near East	Various	8500–8000
Established mixed farmers	Middle PPNB and later	9800–8500
Early stages of domestication	Early PPNB	10,500–9800
Cultivator/hunters, pre-domestic cultivation	PPNA and Khiamian	11,700–10,500
Cereals, small seed gathering, climatic deterioration	Early/Late Natufian	13,000–11,700
Sedentary villages, cereal gathering	Early Natufian	14,500–13,000
Cereal and wild grass gathering (broad spectrum)	Kebaran	23,000–14,500

Levant than this one surviving site suggests. Ohalo II was inhabited during the Glacial Maximum when climate conditions to the north in Anatolia would have been severe, which explains the lack of contemporary sites in this area.

The Epipaleolithic: Prelude to Cultivation

Sedentary Villages and the Early Natufian Homeland: 14,500–13,000 BP cal

The term Natufian comes from Wadi an-Natuf and was coined by Dorothy Garrod, Professor of Archaeology at Cambridge University from 1938 to 1952. This period saw a more favorable climate as ice sheets receded from northern Europe. At this time site density increased dramatically in the southern part of the Fertile Crescent. Most archaeologists agree that some sites represent the earliest known sedentary communities (Bar-Yosef 1998). The most spectacular is the site of Malaha located near Lake Huleh in northern Israel. Here archaeologists unearthed the earliest known houses that represent a sedentary way

Near East (Including Anatolia): Origins and Development of Agriculture, Fig. 2 Map of selected sites. Dates are given as a rounded mean for early levels: *green*, sites with pre-domestic cultivation; *red*, early instances of morphological domestication; however, some need to be verified

of life. Excavations revealed a house of more than 7 m in diameter made of large stone blocks. Stone mortars, probably used for processing grain, 40 cm in height and weighing over 20 kg, were found at Malaha. Unfortunately no plant remains were recovered, but at contemporary sites in the region such as Wadi Hammeh and Hayonim, a few charred cereals were recovered, leaving little doubt that plant gathering similar to that of Ohalo II was still in use. The only site in Anatolia for this period is Pinarbashi which is situated in a rockshelter. It is interpreted as being inhabited by highly mobile hunter-gatherers.

Climatic Deterioration: Late and Final Natufian 13,000–11,700

The late and final Natufian is characterized by a decline in the number of sites in the southern Levant (Bar-Yosef and Vallat in press). For most scholars, this decline is associated with the deteriorating worldwide climatic conditions known as the Younger Dryas (Bar-Yosef 2011). During the 1990s this deterioration was hypothesized as being a major incentive that led foragers to adopt cultivation (see below).

Plant remains in the southern Levant are rare. However, two late Natufian sites in northern Syria occupied during the Younger Dryas have produced rich plant remains. These are Abu Hureyra, situated in arid steppe on the banks of Euphrates and Dederiyeh situated in the Mediterranean maquis less than 50 km from the coast. These two sites have contrasting plant assemblages which reflect the different species of edible plants available in the Mediterranean zone compared to the steppe. At Dederiyeh grains of wild wheats and other wild progenitors dominate the grain assemblage, whereas at Abu Hureyra small seeds from the valley bottom such as members of the knotweed family and small-seeded grasses are the most frequent (Table 2, Fig. 3). Nuts of terebinth are common at both sites, and at Dederiyeh almonds are also frequent. Cultivation during this period has been suggested by more than one scholar. But the plant assemblages at these sites suggest that local gathering was dominant and solid evidence for cultivation is not forthcoming (Colledge and Conolly 2010). However, small-scale cultivation should not be ruled out, although it would leave little or no recognizable trace in the archaeological record.

Pre-Pottery Neolithic: The Early Farmers

Pre-Domestic Cultivation, Khiamian and PPNA, 11,700–10,500

Not all scholars agree on the dating of the early Neolithic periods. The year 11,700 BP cal. is used here for the end of the Natufian; it corresponds with the Younger Dryas/Holocene boundary and the beginning of the Khiamian period which links the Natufian to the PPNA. It was named after the site of el Khiam, where notched arrowheads, characteristic of this period, were first found. Khiamian sites and plant remains are rare. But layers dated to this period at Mureybet (Ibáñez 2008) and Tell Qaramel, located, respectively, not far from late Natufian Tell Abu Hureyra and Dederiyeh, produced plant assemblages similar to their Natufian counterparts although they existed almost a millennium later. After 11,300, PPNA sites are more numerous and many have rich finds of charred plants. Six sites in the southern Levant and five in the northern Levant provide evidence that the subsistence economies were becoming more and more reliant on pre-domestic cultivation (Willcox et al. 2012).

Cereals and pulses, the founder crops, become more common than plants that were not domesticated (Table 1 and Figs. 2, 4, and 5), although this is not the case at Korkik Tepe and Halan Çemi. At Jerf el Ahmar, a gradual reduction in gathered plants from lower to upper levels can be seen. Small-seeded grasses such as *Stipa* and Panicoid types are frequent, as well as other small seeds such as members of the Cyperaceae and knotgrass families (Willcox et al. 2008). The decrease in the gathering of these seeds was compensated for by an increase in the use of founder crops, notably barley, emmer, einkorn, lentil, and pea, which were probably cultivated.

Weeds of cultivation or arable weeds are perhaps the best indicators of pre-domestic cultivation (Colledge 1998). These plants thrive

Near East (Including Anatolia): Origins and Development of Agriculture, Table 2 Absolute counts of edible taxa from selected sites in northern Syria and southeast Turkey. All plants are morphologically wild. *Blue highlights* taxa that tend to increase during the sequence, while *green highlights* taxa that decrease and were eventually abandoned. While absolute counts are not reliable when comparing sites, these results have been verified by ubiquities and percentages

when the soil is disturbed by cultivation and have been evolving since the Neolithic. The number of species increased as agriculture spread into new habitats. Charred weed seeds are common on PPNA sites. The number of arable weed taxa occurring on PPNA sites is equal to or in some cases higher than that found on middle PPNB agriculture sites (Fig. 4).

Grain size increased during the PPNA, particularly in the case of barley, for example, at Jerf el Ahmar and Zahrat adh-Dhra (Fuller 2007). This is often cited as a sign of morphological

domestication. However, a phenotypic increase in size resulting from improved growing conditions is an alternative explanation.

Another indication of pre-domestic cultivation is the introduction of crops into areas outside their natural habitats. Thus, rye and two-grained einkorn were the only cereals present at Natufian Abu Hureyra. By the PPN, barley, single-grained einkorn, and emmer had been introduced in that order at Jerf el Ahmar and Dja'de. Then pulses, notably broad bean and chickpea, appear for the first time far from their natural habitats. At Zahrat adh-Dhra in the Jordan Valley, emmer was common, but the site is situated in an area too dry for this crop to grow naturally.

That cereals became increasingly important during the PPNA can be seen not just from the archaeobotany but also from tools such as querns and sickle blades and from storage structures (Willcox and Stordeur 2012). At Jerf el Ahmar large area excavations provided a wealth of information for large-scale cereal exploitation (Fig. 6). Cereals were a major component of the diet; over 15,000 remains of charred wild barley, wild rye, and wild einkorn were identified. This represents more than half of all the seed and fruit

Near East (Including Anatolia): Origins and Development of Agriculture,
Fig. 6 Examples of large-scale cereal use. *Top left*, burnt daub from a roof structure with cereal chaff impressions; *left*, wall with stones that was covered with a thick render of building earth which contained cereal chaff, examples from Jerf el Ahmar. *Middle left*, latex cast of building earth showing the impressions left by cereal chaff which had decomposed. *Middle right*, one of many buildings which contained several querns. *Bottom left*, two basalt querns from Jerf el Ahmar; *right*, collection of querns left after the excavations at Beidha (early Neolithic site in Jordan), photo 1985

remains from the site. But the archaeological evidence for cereal use is equally impressive. Querns used for grinding cereals were found in situ in buildings, frequently occurring three to a room, suggesting that grinding was being practiced in an organized manner, three querns being used simultaneously in a single architectural and social unit. This suggests that cereal processing played an essential role in the everyday economy of the site, and was probably intertwined with the social structure of village life. In addition, chaff, the residue of processing, was used in vast quantities as a tempering medium in the daub constructions. Examination of large quantities of burnt building earth at Jerf el Ahmar, Tell 'Abr, and Mureybet revealed perfect impressions of chaff, consisting of awns, glumes, lemmas, and spikelet bases. Chaff was systematically added to building earth to reduce shrinkage and increase strength. This technique is still used today in many parts of the world, including northern Syria. Chaff must have been available in massive quantities, given the size of the buildings at Jerf el Ahmar and the fact that they were regularly maintained, destroyed, and rebuilt. The quantity is surprising if we take into account that the de-husking of hulled cereals, particularly barley, produces a low proportion of chaff to grain.

Large-scale collective storage of grain occurred in communal buildings at Jerf el Ahmar, Tell 'Abr, and Dr'a in the Jordan Valley. Not surprisingly, rodent infestation by the familiar domestic mouse (*Mus musculus domesticus*) occurred. These animals left gnaw marks on objects, charred droppings, and their bones and teeth. Evidence for domestic house mice has been found in the southern Levant at Hyonim B and Netiv Hugdud and at several sites in the north.

Sickle blades used for harvesting show an increase in the intensity of use. This is revealed by the characteristic gloss caused by the buildup of a film of plant silica on the cutting edge of the tool (Ibáñez 2008). At Jerf el Ahmar and contemporary sites on the Euphrates, there is an increase in both size and quantity of these tools compared to earlier sites.

In conclusion, the inhabitants at most but not all of the small PPNA villages were cultivators; however, there is no evidence of herding. These societies hunted big game such as aurochs, equids, gazelles, and small game, including birds. The bones of these animals are very common, suggesting that meat was an important element in the diet. These hunter-cultivators were found across the Levant. In northern Iraq cereals and pulses were also in use, although it is not known whether they were cultivated or not.

Expansion into Cyprus and Central Anatolia: The First Signs of Morphological Cereal Domestication in the Early PPNB 10,500–9700

During this period, emmer, einkorn and probably pulses were introduced to Cyprus. Whether or not they were already domesticated is not known. This represents the first sign of cultivators expanding into new territory. The site of Klimonas, dated to the beginning of the early PPNB (or the end of the PPNA) at about 10,600, is the earliest site with cereals on the island. The inhabitants hunted local wild boar. Some three or four centuries later at the sites of Shillourokambos and Mylouthia, cattle, sheep, goat, and other animals were introduced. With this agricultural package came the domestic mouse, presumably introduced accidentally with grain supplies. The introduction of mice implies that large quantities of cereals were being regularly imported.

Expansion towards the north appears to have been limited by the Taurus Mountains until the early PPNB. Cafer Hüyük is the earliest site found beyond the Cilician Gate (Gülek Bogazi), where the Euphrates cuts a gorge through the Taurus.

To the west, recent excavations in central Anatolia at Aşıklı Höyük and Bonçuklu, where a phase with sunken oval houses has been unearthed, have demonstrated that cultivation and herding were developed in this area during the early PPNB. These sites are culturally distinct from those to the east suggesting that agriculture developed independently in central Anatolia rather than being introduced from the east.

Cereals and herding have been identified at early PPNB sites farther east in the Zagros foothills such as Ganj Dareh, Chogah Golan, Tepe

Near East (Including Anatolia): Origins and Development of Agriculture, Fig. 7 The site of Aşıklı Höyük in central Anatolia showing the almost urban nature of this settlement (photo Research Project). Similar settlements in terms of surface area and density of habitats can be found in middle PPNB levels at Halula and Tell Abu Hureyra. These settlements developed as a consequence of a production economy

Abdul Hosein, and Chia Sabz, dated to between 10,250 and 10,500. This suggests as in the case of central Anatolia that agriculture developed locally, probably derived from PPNA sites in northern Iraq.

Morphological domestication of cereals and the first signs of herding appear during this period. Wheat and barley domestication can be identified by the loss of the dispersal mechanism. This is visible in archaeobotanical specimens when the abscission scar is examined; part of the upper spikelet adheres to the scar, indicating the artificial break of domestic cereals. Possible finds of domestic einkorn have been reported from sites such as Nevalı Çori and Cafer Höyük in the northern Levant. At the time of writing, the dating and the domestic status of these finds need to be reexamined. In the southern Levant at Aswad, the earliest levels, dated to the early PPNB, contain domestic barley and possibly emmer wheat. Domestication of emmer and barley was also reported at Wadi el-Jilat 7 and Ain Ghazal.

In conclusion, cereal domestication was not fully established because high proportions of wild spikelets were still present. Agriculture was in the process of developing independently in five geographic regions: southern Levant, northern Levant including eastern Anatolia, Cyprus, central Anatolia, and the Zagros foothills of Iran and Iraq.

Fully Established Farming and Later Expansion: 9700, Middle PPNB, and Beyond

Continuity between the early PPNB and the middle PPNB is poorly documented. Whether this is due to a hiatus or to the fortuitous nature of archaeological discoveries is not known. Whatever the case, by around 9700 large settlements developed which included more than ten times the surface area of the early PPNB and PPNA sites (Fig. 7). These settlements were totally dependent on agriculture; gathering and hunting were minor secondary activities. Emmer wheat, hulled barley, lentils, peas, chickpea, and broad bean became the dominant crops across the whole region in the same way that cattle, sheep, goat, and pig became the norm. No doubt other crops that have left no remains were also cultivated. Both crop plants and animals have domestic morphologies but wild specimens persist. Middle PPNB levels at Aşıklı Höyük, in central Anatolia, and at Halula and Abu Hureyra in the northern Levant or late PPNB levels at Ain Jammam, Baster, Ain Ghazal, and as-Sifiya in the southern Levant represent fully established agricultural communities of near-urban dimensions.

Agricultural expansion out of the Near East is poorly understood at the time of writing, with the exception of Cyprus, mentioned above. The dates for early farming settlements elsewhere are controversial and likely to change in the future; those

presented here are given as ranges or rounded off. It was not until more than a millennium and half after the establishment of agricultural settlements in the Near East that farming villages appeared in new areas. As we have seen, early Neolithic settlements occurred in Iran; further expansion east is illustrated by two sites dated to between 8400 and 8000 in which emmer, einkorn, barley, sheep, and goat were found: Mehrgarh in southern Pakistan and Jeitun in Central Asia. To the west across the Bosphorus, in Thrace and northern Greece, the earliest farming sites dated to between 8300 and 8000 BP cal. Farther north, the Caucasus sites in Armenia dated to about 8000, while to the south, the earliest farmers in Egypt were cultivating the land about 7500.

Key Issues/Current Debates

The question of whether agriculture in the Near East originated at a single center and subsequently diffused rapidly outwards, or was a protracted process occurring simultaneously across the region, has been much debated. In the 1960s and 1970s, Jericho was considered the key site from which agriculture diffused. By 2000, a small area of southeast Anatolia was seen by agronomists as being the core area; their hypothesis was based on the present-day distribution of wild progenitors and DNA fingerprinting of modern einkorn wheat, rather than archaeology. This hypothesis has been questioned, because in the surrounding regions pre-domestic cultivation predates sites in the so-called core area (Fuller et al. 2011). While some crops may have originated in southeast Anatolia, for example, chickpea, archaeology clearly shows that in adjacent regions (see map), local wild populations were taken into cultivation as early as or earlier than in southeast Anatolia.

Another debate which concerns agronomists and geneticists concerned with biodiversity has been about whether the major crops were taken into cultivation just once or many times. These researchers wanted to know whether today's crops are monophyletic or polyphyletic in origin. The first DNA studies on einkorn in 1997 suggested monophyletic origins. However, subsequent studies are not so clear-cut; other crops such as barley show polyphyletic origins. Studies of modern populations cannot provide the full story because many cultivars have become extinct over the last 10,000 years. For the moment, the debate continues as new information accumulates.

Identifying domestication is an important issue for the origins of agriculture, and not all researchers agreed on the criteria. Van Zeist recognized in 1984 that the earliest domestic populations contained significant proportions of wild specimens. This was later confirmed at several other sites (Tanno and Willcox 2006). This discovery led scholars to question earlier hypotheses proposing that domestication could have occurred rapidly in a few generations. It is now generally accepted that domestication was a slow, protracted, and continual process. PPNA societies took local wild wheats and barleys into cultivation in widely separated regions, and domestication occurred more than once and independently in those different regions.

What were the factors that caused hunter-gatherers to become farmers? This debate has been going on since the 1920s. On the one hand, there are determinists who see natural phenomena as being the catalysts, while on the other, there are those who regard an increase in cultural complexity as the catalyst. But was increased sociocultural complexity the cause or was it the consequence of adopting agriculture? (Watkins 2010). Given the time scale and the geographic and climatic diversity across the vast region inhabited by late Pleistocene/early Holocene societies, factors like climate change, population increase, over-exploitation of resources, and societal developments would have played more or less important roles at different times and different places. With regard to climate change, several researchers have suggested that sustainable agriculture would have been difficult during the late Pleistocene but that the more stable conditions of the early Holocene favored agriculture (Fig. 8) (Willcox et al. 2009). The debates continue as new discoveries are made.

Finally, brewing has been mentioned as a possible use for cereals from the Natufian onwards (Haaland 2007). While the idea may seem

Near East (Including Anatolia): Origins and Development of Agriculture, Fig. 8 The *black curve* gives average worldwide changes in oxygen isotope 18 which reflects global temperatures. Postglacial warming coincides with the increase in density of sites in the southern Levant while the Younger Dryas cooling with decreased density. Holocene warming coincides with the development of PPNA sites and pre-domestic cultivation. The *red curve* gives shorter-term amplitude changes in temperature which are greater during the Pleistocene suggesting unstable climatic conditions. At the start of the Holocene, changes are less severe indicating more stable climate conditions. Several scholars suggest that durable agriculture would be more viable with the stable climatic conditions of the Holocene

N

attractive, the arguments are speculative, and at the time of writing, there is no factual scientific evidence for brewing in the Near East for the Natufian or PPN periods.

International Perspectives

The Near East is just 1 of at least 11 and perhaps over 20 regions where agriculture developed independently around the world. While it is often considered to have been the earliest known center where farming developed, it is possible that cultivation was adopted in tropical regions during the Pleistocene although little evidence has survived. Taphonomic factors have an effect on the international perspective concerning the origins of agriculture. Non-charred plant materials, including pollen, decompose and oxidize readily in aerobic archaeological sediments, while anaerobic or desiccating conditions are very rare. The semiarid conditions of the Near East favor the preservation of inert charred plant remains because bioturbation and mechanical abrasion are minimal. Thus, the Near East has provided far more information than other regions.

The distribution of archaeological research for the Near East is uneven. Survey coverage of the Near East is irregular; there are vast areas which have not been surveyed. Dam construction on the Euphrates has led archaeologists to carry out numerous rescue excavations in the valley between 1970 and 2000, favoring this area. And of course changing political situations in the lands of the Near East have affected research into the origins of agriculture.

Future Directions

The discovery of new sites in the future will have impact on our view of the origins of agriculture in the Near East, as have the exceptional discoveries of the past few decades. These discoveries are often fortuitous because systematic surveys are lacking in all areas. Detailed systematic survey work in the future will no doubt bring to light new sites, especially in more remote areas. Satellite imagery will no doubt become a useful tool for surveying, but must be backed up by ground surveys.

There is room for improvement in the accurate identification of charred plant remains. Weeds are often only identified to genus and so can only be defined as assemblages. Extinct cereals like the new glume wheat are being recognized, and this aspect will no doubt be developed in the future. So far ancient DNA has been found to be too degraded in specimens of plant remains from the Near East. New techniques may make breakthroughs possible in the future.

Climate data from locations in the Near East are very limited and often poorly dated. Future studies of natural climatic archives such as lake, marine, and cave sediments will provide more accurate data for paleoclimate research.

Nemrud Dağ, Archaeology of

Miguel John Versluys
Department of Classical and Mediterranean Archaeology, Faculty of Archaeology, Leiden University, Leiden, The Netherlands

Introduction

Nemrud Dağ (alternatively spelled as Nemrut Dağ or Nemrud Dağı) is a Taurus mountain with a height of 2,205 m in southeastern Turkey (province of Adıyaman) in the northern part of a small region at the Euphrates that was known as Commagene in antiquity. The burial site of King Antiochos I of Commagene (69–36 BCE) is located at its summit: a temple-tomb (*hierothesion*) designed to be the focal point of a highly original and typical late-Hellenistic project of dynastic self-presentation extending throughout the entire kingdom. The *hierothesion* has never been in use, and its completion was probably hurried along in an improvised manner soon after Antiochos I died; it should be dated, therefore, roughly between 50 and 35/30 BCE. The actual tomb of the king has been searched for intensively, but it has not been found as yet. Nemrud Dağ is remarkable for the fact that it has preserved a highly standardized *Bildprogramm* juxtaposing so-called "Greek" and "Persian" (or "Iranian") elements. The king himself provides a motivation for this through an extensive "foundation text" executed as a monumental inscription at the site itself.

In this entry, Antiochos I characterizes his *hierothesion* as "the throne of the gods," which it is in literal sense (see below). As such, in recent decades, the spectacular site of Nemrud Dağ has been developed into one of Turkey's most important archaeological landmarks, also with the incentive to draw tourists into a relatively poor and underdeveloped area. The issue of stakeholders at this UNESCO World Heritage Site therefore presents a complicated case. Already at the end of the nineteenth century, a German expedition (led by Carl Humann and Otto Puchstein) and an Ottoman expedition (led by Osman Hamdi Bey) competed with each other to claim the site's scientific "discovery" and publication. After WWII, the American archaeologist Theresa Goell worked at Nemrud Dağ while the rest of Commagene, most notably Arsameia ad Nymphaios (see below), was the focus of the work of German epigraphist Friedrich Karl Dörner from Münster, who founded the *Forschungsstelle Asia Minor*. Nevertheless, both scholars collaborated throughout their projects; Münster remains the home of Commagene-studies today. During the past decade, an international team under the aegis of the University of Amsterdam (the Netherlands) worked on the conservation of the site, soon followed by a Turkish team from the Middle East Technical University with the support of a major EU grant. Unfortunately, these recent efforts have not resulted in a satisfying heritage plan, and the monument is still under threat.

Definition

Nemrud Dağ and Commagene

The site consists of three terraces around a tumulus, which has been transformed into a prominent landmark by means of covering the original mountain peak with a layer of artificial gravel. The tumulus was visible from large distances, and because of this visibility, we may assume that Antiochian kingship made itself felt throughout Commagene (Figs. 1 and 2).

This was strengthened by the fact that mountain peaks in the vicinity of important Commagenean settlements had similar dynastic sanctuaries – although generally, these were smaller, less complex, and did not always contain a royal tomb. Nemrud Dağ was therefore part of a kind of "grid" of dynastic self-presentation spanning the whole of Commagene.

Of the three terraces surrounding the tumulus, the East and West terraces are the most prominent; these could be reached from the valleys below via marked processional roads. The so-called North terrace, more like a passageway connecting the East and West "courts," was apparently intended to display a large number of stelae, but only their sockets were put in place, and the project was left unfinished. The East terrace was the most spacious area around the tumulus (around 500 m^2), and its condition has been explored to the full. Rising above the terrace and almost placed against the tumulus, a group of five colossal (originally 8–10 m high) statues were found, flanked at both sides by animal groups consisting of a lion and an eagle (Fig. 3).

The statues are built up by dry-stone masonry consisting of large blocks of yellowish-white limestone in six to eight horizontal layers. Due to earthquakes, the heads of the statues have broken off and fallen down onto the terrace – recently, they have been placed in a row in front of the statues. The monumental inscription, inscribed at the back of the colossi, identifies the figures that are displayed (Fig. 4).

Centrally positioned is Zeus-Oromasdes flanked (at the north side) by Apollo-Mithras-Helios-Hermes and Artagnes-Herakles-Ares and (at the south side) by the goddess Commagene (a personification of the region) and Antiochos I himself. The king thus places himself amid those whom he apparently upholds as the main gods of his pantheon. For a Hellenistic ruler, it was not unusual to claim divinity and to be worshipped as a god. In Egyptian temples, for instance, the Ptolemies received libations and incense as *synnaoi theoi* (temple-sharing deities): the same was intended to occur at Nemrud Dağ. However, the "double identity" of the gods seems remarkable here: they are designated simultaneously as "Greek" (e.g., *Zeus*, the main deity of the Greeks) and "Persian" or "Iranian" (e.g.,

Nemrud Dağ, Archaeology of, Fig. 1 Plan of the site. (After the forthcoming book by H.A.G. Brijder, with permission)

Oromasdes, the main deity of the Persians). The style of the statues seemingly aims for a similar kind of "blending of West and East" and is therefore often defined as "Greco-Persian." This practice seems visible also in the so-called *dexiosis* reliefs, placed before the colossi toward the terrace. On these, the king is portrayed in a very "Eastern" attire (with the Armenian *tiara*, Persian boots, and regalia like a sash) shaking hands with, in one example, a distinctly nude and "Greek" Herakles (Fig. 5).

Originally, the so-called Lion horoscope was also part of this sculptural ensemble: a relief showing a lion with specific stars and planets scattered all over and representing an astronomical constellation. On the East terrace itself, the

north and south sides are lined with a "wall" of large reliefs displaying the "ancestors" of the king. Here Antiochos I expresses his wish for double identity through genealogy by claiming that he descends from the Achaemenids (and ultimately the "king of kings" Dareios) from his father's side and, via the Seleucids, from the Macedonian royal house (and ultimately Alexander the Great) from his mother's side. The reliefs show and identify these ancestors (15 "Persian" and 17 "Greek"), who are all portrayed in a very recognizable "Greek" or "Persian" style. All these elements (the colossal statues of the four gods and Antiochos I, the *dexiosis* reliefs, the Lion horoscope, and two rows of ancestor reliefs) are also encountered on the West terrace. There, however, was less space available: the *dexiosis* reliefs were therefore placed next to the statues, and the Seleucid and Macedonian "ancestors" were placed opposite the colossi. The original situation has not been as well preserved as on the East terrace, as the colossi have entirely collapsed.

The other dynastic sanctuaries throughout Commagene – designated as *hierothesion* when a royal tomb would be present, otherwise simply called *temenos* – shows (selections of) a similar repertoire of text and material culture. This was standardized to such an extent that when fragments of the monumental inscription (or related texts) are found, they often can immediately be recognized as (part of) paragraph *x* or *y*. This does not mean, of course, that variation was impossible, as is illustrated by archaeological finds from Arsameia ad Nymphaios, a site relatively near Nemrud Dağ that has been explored by a German team in the 1950s, 1960s, and 1970s. Inscriptions from Antiochos I claim that here his father, Mithridates I Kallinikos (c. 100 BCE–70 BCE), was buried and that Antiochos I established a cult for him. At Arsameia ad Nymphaios, there were also colossi and *dexiosis* reliefs and cultic proscriptions like at Nemrud Dağ, but the role of Mithras seems to have been more prominent. On the main plateau, banqueting rooms were found corresponding to the Hellenistic Mediterranean

style of the period; at Nemrud Dağ, we do not have such buildings. Next to the banqueting rooms, the excavators place the royal temple-tomb for Mithridates I Kallinikos in the dynastic "Greco-Persian" style; the archaeological evidence is scant due to a thorough destruction by later building phases.

Current Debates and Future Directions

There are three key issues for the archaeology of Nemrud Dağ and Commagene.

The first revolves around value judgments and what one could call a "contextual, Hellenistic understanding" of the material. Antiochos' project of dynastic self-presentation is often interpreted negatively, as a failed attempt. This would become clear also from the "hybridity" of the Antiochian style – with the word hybrid intended as a pejorative qualification. Illustrative is the remark by Bert R.R. Smith (Smith 1985: 275) that Antiochos I "suffered probably from both paranoia and megalomania." Through this approach, Nemrud Dağ has been written out of Hellenistic archaeology and history as something marginal and non-representative. Other research, however, stresses the originality and ingenuity of the Antiochian project and sees its eclecticism as typical for the late Hellenistic period. The mausoleum of Augustus, for instance, could be argued to constitute a remarkable parallel to Nemrud Dağ in rather more structural terms. Visibility within the urban landscape was applied as a major instrument for dynastic display by Augustus, who also used a canonical text (the *res gestae*), a colossal statue, and a strong focus on genealogy. This resulted in a monument that was stylistically highly eclectic, as was Nemrud Dağ. Be that as it may, the archaeology of Nemrud Dağ would certainly profit from taking its object more seriously and trying to understand Commagene as one of the many "centers" of Hellenistic *koine*. Such an approach is strengthened by recent archaeological finds showing that this rich and strategically positioned kingdom at the Euphrates was not at all a cultural backwater but a fully fledged part of the Hellenistic Mediterranean and Near East.

The second key issue revolves around the nature of the sources to our disposal. These are often imagined as "ausnehmend gut" (Schwertheim 2005: 77) because of the availability of texts as well as material culture from a relatively securely dated historical context that, moreover, would add to an interconnected understanding of both. For archaeology, this has resulted in a dominant influence of the texts in historical and archaeological interpretation. However, (almost) all our sources are part of the program of display designed by Antiochos I and are therefore likely to provide us a dynastic image, but not a historical reality. Moreover, there is (almost) no evidence that is *not* part of this Antiochian program. In other words, we cannot check or contextualize his "propaganda." It could be argued, therefore, that our sources are in fact not good at all as they are extremely one-sided and (potentially) misleading. The gravity of this matter becomes clear from the excavations at Arsameia ad Nymphaios. In the texts from this site, Antiochos I boasts to have substantially enlarged and enriched an older Commagenean settlement (mentioning new royal palaces, a water supply, a military base, etc.), but more than two decades of investigations led by Friedrich Karl Dörner (from 1953 to 1976) failed to find any of these nor does there seem to have been a pre-Antiochian phase. The archaeology of Commagene, therefore, has an unstable foundation seeing that it has so far focused solely on the dynastic monuments. No first-century BCE Commagenean village or city has been excavated; its capital Samosata (Samsat) has only been provisionally explored and published and is now beneath the waters of a large reservoir; there is (almost) no epigraphical record outside the Antiochian texts; no intensive field survey has been undertaken. In other words, we do not really know what the relation was between the thoroughly Hellenistic project of dynastic display and the social context in which it was supposed to function, as that context is simply not available. This is one of the reasons why the recent work by

Engelbert Winter (Münster) and his team in Doliche is so important: here we have an Antiochian *temenos* that stood in relation to an older cultic context.

The third and final key issue for the archaeology of Nemrud Dağ and Commagene is how to understand this "coming together of East and West at the Euphrates" theoretically. Most scholars argue, often implicitly, that we would deal here with acculturation processes like Hellenization and Persianization. The topographical position of Commagene is thus considered to be the key to the understanding of its material culture: "East" and "West" literally seem to meet here. For instance, Bruno Jacobs (Jacobs 2003), the author of a series of important interpretative articles on the archaeology of Nemrud Dağ and Commagene, assumes the existence of Greek and Persian elites in society. Antiochos I would have tried to reach and integrate these groups by means of his double-styled language of images. Such a hypothesis, although well imaginable, is difficult to prove seeing that we know so little about late Hellenistic Commagenean society (see key issue 2). Moreover, if we take Nemrud Dağ seriously as Hellenistic *koine* (see key issue 1), other strands of interpretations emerge. Referring to things "Greek" and "Persian" seems in the first place to have to do with cultural memory and invention of tradition, as in the first century BCE, neither Greeks nor Persians were a real (political) factor anymore whatsoever. However, as cultural concepts, "Greek" and "Persian" styles and elements played an important role within the Hellenistic world and its *koine*. It is perhaps more likely, therefore, that we should try and interpret the "Greek" element not in terms of Hellenization but in terms of *Hellenism* and the "Persian" element not in terms of Persianization but in terms of *Persianism*. Taking up these kinds of elements because of the meanings and associations they had acquired over time and putting them together in innovative combinations are typical for the culture of late Hellenistic *bricolage*. From this perspective, Nemrud Dağ could be argued to be a most significant case study for the archaeology of the (late) Hellenistic world, as it attests to the first-century BCE eclecticism that Augustus would use to create the canon that we call Roman. It is Wolfram Hoepfner (Hoepfner 2000) who first seems to have realized this perspective to a full extent. In general terms, the Hellenism and Persianism of Antiochos I can be explained as follows. "Doing Greek" was the way for a local dynast to show that he was significant (or wanted to play a role) on the Hellenistic stage, as Hellenism simply was the language of culture and modernity. "Doing Persian" was the way to claim dynastic legitimacy in a region where the Achaemenids were the last uncontested rulers of a true world-empire. There is certainly a lot more to explore from this perspective, an important point of discussion being the fact that the dynastic program of Antiochos I seems to have been targeted more toward his rival Hellenistic kings than toward the population of his small kingdom. But we can only do so when Nemrud Dağ is given a more central place in the archaeology of the Hellenistic and Roman Near East. Given the large array of important discussions to which Nemrud Dağ seems able to contribute (to name but a few: the functioning of Hellenistic *koine*, Hellenism and Persianism in antiquity, dynastic propaganda and the language of images, the divinity of Hellenistic rulers, Romanization in the East, the contextualizing of the Augustan cultural revolution), it certainly deserves that place.

The work by Theresa Goell from the 1950s, finally published by Donald H. Sanders in 1996, remains the most important point of departure for the archaeology of Nemrud Dağ itself (Sanders 1996). It is best consulted together with the review by Bruno Jacobs (Jacobs 1998). For recent work by the international team, see the articles by Eric M. Moormann and Miguel John Versluys and the final report edited by Herman A.G. Brijder (2014); for the most recent Turkish project on the site, see contributions to Winter (2011). The best general introduction to the archaeology of Nemrud Dağ and Commagene is Wagner (2000) now with Brijder (2014). All historical information on Commagene, Antiochos I, and his dynasty has been assembled in Facella (2006). Margherita Facella, Bruno Jacobs, and Jörg Wagner have published important interpretative essays on Antiochos I and his dynastic program. The best

introduction to the epigraphic source material is now Crowther and Facella (2003) (with full bibliography). Arsameia ad Nymphaeum has been published in two volumes: Dörner and Goell (1963) and Hoepfner (1983). Ongoing work in Doliche is published in the *Istanbuler Mitteilungen*, so far in volumes 55 (2005: 191–214) and 56 (2006: 185–205); see most recently several articles in Winter 2011 and contributions to the most recent volumes of the series *Asia Minor Studien* like Winter (2014). Michael Blömer and Engelbert Winter have now published (Blömer and Winter 2011) an up-to-date archaeological guide of Commagene with all basic information and full bibliography. Several volumes of the series *Asia Minor Studien* deal with Commagenean archaeology specifically, most recently Winter (2008, 2011, 2014). Merz and Tieleman (2012) contains several articles dealing with the question of commagenean identities in the first century BCE and the first century CE;; fundamental for that debate now Blömer 2014; a rich catalogue and thorough interpretation of the stone reliefs from the Roman period. I have tried to describe Nemrud Dağ from a wider Hellenistic perspective in terms of *bricolage* using Hellenism and Persianism (Versluys 2013, 2017).

Netherlands: Cultural Heritage Management

Monique H. van den Dries
Faculty of Archaeology, University of Leiden, Leiden, The Netherlands

Introduction

In the Netherlands, the professional archaeology had its start in 1818 with the appointment by the national government of Caspar Jacob Christiaan Reuvens as archaeology professor at the University of Leiden and as the director of a national museum for antiquities that he had to develop. Reuvens (1793–1835) was actually the first university professor of prehistoric archaeology in the world (Brongers 1973). It was however already long before this that a concern for the preservation of archaeological phenomena had emerged. That happened in the 1730s, when the best-known Dutch monuments, the *hunebedden* (megalithic burial chambers of c. 3400 BCE–2850 BCE), became endangered due to a massive attack of shipworms (*Teredo navalis*) on the Dutch coastal defenses. As these "termites of the sea" were eating the piles in the dikes, loads of heavy stone material was needed to restrengthen the dikes. Poor inhabitants of the province of Drenthe saw in this an opportunity to earn some money by collecting and selling the free stone material that was abundant in the boulder clay soil in the North. But the *hunebedden* also provided a rich source for heavy stone material and were dismantled rapidly. When the provincial government of Drenthe realized what was at stake, they announced on 21 July 1734 a resolution to protect the tombs against stone digging (Brongers 1976). Even a pecuniary punishment of 110 gold guilders could be imposed. With this, the first monuments legislation was a fact, and it can be considered the start of cultural heritage management in the Netherlands. Since then the approach has obviously been altered drastically. Especially in the last two decades, when market-driven development-led archaeology was introduced, a complete transformation of Dutch heritage management has been witnessed.

Key Issues/Current Debates/Future Directions/Examples

The first legal provisions to preserve the archaeological heritage did not have much effect. The destruction of the *hunebedden* continued, because the risk of being caught was low and very few people were fined. Even governments seemed to have used stone material from the megalithic structures, for instance, to improve roads. When in 1818 a first formal inventory of the burials was made, it was clear that additional protective measurements were needed. These were effectuated as of 1846 when the provincial and national government started to purchase the sites. By 1872, a total of 45, nearly all that remained, was owned by the authorities. These, and eight others that were added afterward, have all been preserved till the present day (Rijksdienst voor het Cultureel Erfgoed 2009).

Although in a way effective, this type of protection was clearly not systematic and structural. The state's and professional archaeology's main interest concerned scientific research, to learn about the material culture through excavations and collecting finds. Reuvens, for instance, initiated a national documentation of archaeological sites (Willems 1997), but his focus and that of succeeding archaeologists like Jan Hendrik Holwerda (1873–1951) and Albert Egges van Giffen (1884–1973) was on developing excavation methods. For instance, as curator of the Drents Museum in Assen, Van Giffen was assigned in 1919 by the Minister of Education, Art and Science to make an inventory of the condition of the remaining megalithic tombs and to do some restoration works, but these preservation activities were restricted to these most prominent archaeological phenomena and had an incidental character (Fig. 1).

Growing Awareness

A first step toward a more systematic focus on preserving the archaeological heritage was the

Netherlands: Cultural Heritage Management, Fig. 1 One of the 53 remaining *Hunebedden*. Their rapid destruction in the eighteenth century raised awareness that the archaeological remains needed protection of the authorities. (Photo: M.H. van den Dries)

initiation, on 24 May 1940, of a national advisory committee (Rijkscommissie voor het Oudheidkundig Bodemonderzoek) and an office for the archaeological heritage (Rijksbureau voor het Oudheidkundig Bodemonderzoek, RBOB). Besides documenting finds, one of the first tasks of the office was to list the artificial dwelling mounds (*terpen*) in need of protection. At that time, it had just become clear that these artificial dwelling mounds, which were constructed in the north of the Netherlands from c. 500 BCE to protect people and cattle against the sea, were even more threatened than the *hunebedden*. They consisted of very fertile soil, which was harvested intensively to fertilize the poor sandy soils in other parts of the country (Fig. 2). This exploitation had started slowly in the 1850s, became very popular as of the 1870s, and had its peak in the 1920s (Rijksdienst voor het Oudheidkundig Bodemonderzoek 2002: 17). So, when in 1943 the exploitation of the *terpen* was finally legally restricted and the RBOB made its inventory, it turned out that, for instance, the province of Friesland had already lost more than 75% of its original 910 dwelling mounds (Halbertsma 1963). Thanks to this protection policy, approximately 350 dwelling mounds are preserved. In fact, dwelling mounds are one of the best represented categories on the list of nearly 1,800 national monuments (Rijksdienst voor het Cultureel Erfgoed 2009: 31).

The need for a more systematic care for monuments became even more apparent after the Second World War, when war-damaged historical buildings and the archaeological remains in the subsoil had to be protected against massive reconstruction activities. So, in 1947, two new state agencies were founded for this purpose, one for historic buildings (Rijksdienst voor de Monumentenzorg, RDMZ) and one for archaeological research (Rijksdienst voor het Oudheidkundig Bodemonderzoek, ROB) (Willems 1997). Van Giffen became the director (1947–1949) of the latter. Although he kept his chair at Groningen University and became primarily famous for developing excavation techniques, Van Giffen also had genuine preservation motives. For instance, his selection of sites for excavation was often directed by considerations of threat. After his retirement, he even became the first and only State Inspector for the protection and maintenance of *hunebedden* and restored archaeological monuments.

Netherlands: Cultural Heritage Management, Fig. 2 The exploitation of the *terp* of Hogebeintum, 1896. (Source: van den Berg 1981)

Shared Responsibility

The ROB's main task was to make an inventory of all archaeological monuments in the Netherlands and to subsequently take care of their protection and preservation. In practice, this meant that almost all capacity was directed toward rescue excavations. Due to the large scale of postwar reconstruction works, land reclamation projects in the new polders, and the reallotments policy, the ROB was preoccupied with excavating the remains that these activities exposed (Willems 1997). Large numbers of volunteers were hired to assist, but also additional specialist capacity was needed. Thus, in 1954, a nautical archaeological department was established to take care of the shipwrecks that were uncovered in the polders.

Additional digging capacity was also gained from the university departments in Leiden, Amsterdam, and Groningen, and as of 1960, individual municipalities started to establish their own archaeological service (Sarfatij 1990). The first was Rotterdam, that suffered from the most extensive war destruction, but others followed soon. Currently, over 40 municipalities and around 20 regions have an archaeological service (www.gemeente-archeologen.nl). Between the late 1960s and early 1970s, a network of 12 provincial archaeologists was subsequently developed that covered the entire country. This in particular introduced a more continuous and systematic care for endangered archaeological sites.

Successive Monument Acts

A first effective attempt to prevent the rapid destruction of both historic buildings and archaeological sites and to start protecting them was made with the introduction of the Monuments Act in 1961. It defined a monument as immovable property created by man which is more than 50 years old and of general interest on account of its beauty or scientific or cultural value. It required each municipality to draw up a list of historic buildings, and it subsequently banned any alterations to, or demolition of, these listed buildings without the Minister's consent. For the archaeology, the law introduced the obligation to report chance finds and a prohibition on digging without an excavation license.

As it also paved the way for the protection of valuable historical entities such as townscapes, the Monument Act has been rather effective for the protection of historic monuments. In 1970, the monument lists were completed for all municipalities, and in 1980, 42,000 monuments were protected, including over 1,400 archaeological sites. Its success however also resulted in a lack of finances for the maintenance and restoration of all these monuments and very time-consuming

administrative procedures (Van Haaff 2006). It led to appeals against listings by private owners of monumental buildings and a stagnation in new listings. The need for a new way of handling monuments grew, along with a desire to protect other cultural elements as well, like younger buildings and underwater cultural heritage. Thus, a revision of the act was initiated, though it only entered into force in 1988.

The most important change for historic monuments was the principle of decentralization, by which municipalities gained much more authority. Proposals for listings no longer came from the central Monuments Council but from municipalities themselves. For archaeology, the revision meant that sites could be protected better. First, finds were now legally owned by the state (or a municipality with a license and a repository), and sites outside the territory of a municipality, like maritime sites, could be designated as a monument too. Moreover, excavation permits were no longer given to individuals or provinces but to the national service, universities, and municipalities only. In order to gain more control over the archaeological record, such bodies were also obliged to give notice of all excavations and to report the results to the State Service.

International Influence

Although it was clear that the rescue archaeology practice was disastrous for the preservation of the archaeological record, it continued during the 1980s and early 1990s. As the Netherlands were involved in the revision of the Council of Europe's European Convention on the Protection of the Archaeological Heritage of 1969, an attempt was made to integrate the care for the archaeological heritage in the national planning process, but the national law in force, the revised Monument Act of 1988, provided no legal means. This practice only changed after the Malta Convention was signed, in 1992 in Valletta, and authorities started to adapt their policy regarding the archaeological heritage.

As of the 1990s, other international agreements on cultural heritage gained influence on Dutch policies and approaches as well. Until then, only the first protocol of the UNESCO Convention for the Protection of Cultural Property in the Event of Armed Conflict (The Hague 1954) had been signed (in 1958), but after the Malta Convention, the country soon signed the UNESCO World Heritage Convention (1972). This led to the listing in 1995 of the first and so far only archaeological site, Schokland (www.schokland.nl), on the World Heritage list. Subsequently, the Council of Europe's Treaty of Granada (1994) was ratified in 1994, followed by the Convention on the Means of Prohibiting and Preventing the Illicit Import, Export and Transfer of Ownership of Cultural Property (1970) in 2009. In 2016, it was announced by the Ministry of Education, Culture and Science and the Ministry of Foreign Affairs that they had started the ratification of the 2001 UNESCO Convention on the Protection of the Underwater Cultural Heritage.

Implementing the Valletta Principles

The implementation of the Malta convention has had a major impact on the management of the archaeological heritage in the Netherlands. The centralized and state-dominated archaeological system was replaced by a decentralized and liberalized system with a commercial archaeological sector, and archaeological research was integrated in all planning, building, and land development processes. It was implemented in national legislation in September 2007 by means of the *Wet op de Archeologische Monumentenzorg*, WAMZ, which was an amending law that simultaneously adapted all related laws, like the Monuments Act and the Housing Act (http://wetten.overheid.nl/).

Already from 1998 onward, however, when the Dutch Parliament ratified the Malta Convention, the principles of the Malta Convention were systematically applied in case of soil disturbances by the national, regional, or local governments. This rapidly generated a lot of mitigation projects. As the small group of 30 organizations holding an excavation permit could not conduct all the extra work, the State Secretary for Culture, economist Rick van der Ploeg, decided to allow a free market system with a commercial sector for archaeological work (Willems 2005: 50–54). While awaiting this to be implemented in the legislation, an interim policy allowed companies from 2001

onward to "borrow" the excavation license of the State Service.

The ministry acknowledged that instruments for quality management would be needed as well. It was considered a risk that commercial and financial considerations of the archaeological contractors and building companies would prevail over those of the (scientific) quality of the work. Adding rules and regulations was politically only feasible, however, if the archaeological community would take care of some parts of the quality management too (so-called self-regulation). Thus, a mixture of both publicly and privately organized instruments was designed. As the commitment of the archaeological community was needed for the successful development and implementation of most of these instruments, they were developed in concert by a large number of archaeologists (Van den Dries and Willems 2007).

On the public side, an excavation permit and an inspectorate (www.erfgoedinspectie.nl) complemented the Monument Act. On the private side, a quality standard (www.sikb.nl), a professional register, and a research agenda (www.noaa.nl) were initiated. The quality standard describes how the archaeological processes and procedures should be carried out and by whom (Willems and Brandt 2004). The professional register lists the individual archaeologists who, after a peer review, are allowed to take care of these activities. The research agenda sets prevailing scientific research questions.

In 2016, the WAMZ was replaced and incorporated into the Heritage Act. The aim was to integrate the legislation on archaeology with other acts on movable cultural heritage, to improve the system of quality control and – in due time – to simplify all regulation on environmental planning (Krauwer 2015). It implies that excavation permits are no longer granted by the National Agency for Cultural Heritage (www.cultureelerfgoed.nl), the former ROB. They have been replaced by certificates (see www.sikb.nl). Certificates are granted by independent accreditation bodies that have been accredited by the Dutch Accreditation Council.

These instruments are all closely linked. A certificate is, for instance, only granted if a contractor can demonstrate compliance with the Quality Standard and employs qualified archaeologists. The Inspectorate subsequently monitors whether in practice people comply with the legislation and the self-imposed quality measurements. The system gradually has become operational as of 2001, and since July 2016, all elements – including the register – are functioning. The system is completed as originally intended.

Malta in Practice

Due to the revision of the law, care for the archaeological record is now integrated in planning processes, and local authorities have to take known and unknown archaeological remains into account when they define a new or revise an existing development plan. In this development plan, the authorities indicate the valuable archaeological areas in which private developers and property owners are required to conduct (and pay for) validations and impact assessments when they apply for a building permit. In 2009, an inventory showed that 32% of the municipalities had indeed included provisions to protect the archaeological heritage in all their development plans and another 57% in some of their development plans (Erfgoedinspectie 2010: 102).

The local authorities have various moments and instruments to administer the heritage management process. First, the competent authority points out its research demands in a project outline (which in practice is often written by an archaeological consultant). This project outline serves as a basis for the subsequent tendering process, by which the developer selects an archaeological constructor to do the research. The archaeological contractor is obliged to follow the demands of the project outline, and the municipality has the authority to verify whether the demands of the project outline are being followed. Next, the authority takes the assessment results into account when they decide on the building permit and whether a mitigation process must be carried out or whether the terrain will be protected. In case of further archaeological research, the municipality authorizes the site report which contractors are obliged to produce within 2 years after the fieldwork has finished. At the end of the process, the

reports and results are published by the State agency. The finds, soil samples, and documents are kept by the provincial authority.

Some Facts and Figures

The implementation of the Malta principles has had a serious impact. For 2007/2008, it was estimated that 90% of the work is developer-funded (Waugh 2008). In particular, the number of inventories and field evaluations has increased tremendously since 2000 (Fig. 3). The number of excavations remained relatively small, till 2008 just under an annual number of 200 (Van den Dries et al. 2010). It is not known to what extent this reflects "preservation in situ." An inventory by one of the companies shows that nearly 40% of the sites they discovered may have been preserved in situ (Schutte et al. 2011). The heightened attention on the archaeological heritage has however not led to a substantial growth of legally protected archaeological monuments; in 2002, nearly 1,700 were listed and, in 2007, 1,770 (Rijksdienst voor het Cultureel Erfgoed 2009: 29). In 2017, this number had decreased to 1,448 (https://erfgoedmonitor.nl/sites/default/files/views_filebrowser/_def-erfgoedmonitor-jaarcijfers2016-a3liggend.pdf).

Most of field work is carried out by the commercial sector (Fig. 4). At the start of 2011, 19 companies had a license to excavate, mid-2017 30 had obtained a certificate (https://www.sikb.nl/archeologie/certificeren-en-registratie/certificaathouders). Municipalities can still obtain permission to excavate too. At the start of 2011, 23 municipal archaeological services had a license, but they increasingly focus on developing and applying heritage policies and on public outreach activities rather than on field work. In 2017, only 16 had opted to obtain a certificate. In addition, an increasing number of municipalities work together to create a regional archaeological service. It implies that at least 70 of all 318 municipalities (22%) have archaeological knowledge at their disposal. Both municipal and regional services participate in a network, called CGA (www.gemeente-archeologen.nl). Together the sector reported in 2016 nearly 4,000 archaeological activities, including 1,144 desk-based researches and 166 excavations (https://erfgoedmonitor.nl/sites/default/files/views_filebrowser/_def-erfgoedmonitor-jaarcijfers2016-a3liggend.pdf).

Apart from the companies with a license, at least another 100 private companies are active on the archaeological market. Most of them are doing various kinds of activities for which no license is needed, like consultancy, specialist services, presentations, etc. Most of the companies are joint in one of the two branch

organizations, VOIA (www.voia.nl) and NVAO (www.opgravingsbedrijven.nl).

As a result of the emerging commercial sector, employment in archaeological heritage hugely increased from an estimated number of around 800 in 2000 to over 1100 in 2011. It implied that prior to the global economic crisis of 2008/2009, there was almost full employment of the Netherlands' archaeologists. This also attracted large numbers of students for all five universities (Leiden, Groningen, two in Amsterdam, and Nijmegen) where archaeology is being taught. On a yearly basis, around 150 students start an archaeological training at one of the universities (www.vsnu.nl).

Neustupný, Evžen

Peter F. Biehl
State University of New York at Buffalo, Buffalo, NY, USA

Basic Biographical Information

Evžen Neustupný was born in Prague, Czech Republic (formerly Czechoslovakia), in 1933. He studied prehistory and Egyptology at the Charles University in Prague and received his Ph.D. in prehistoric archaeology in 1957. Until 1966, he worked with rescue excavations of endangered sites at the Most branch of the Institute of Archaeology of the Czechoslovak Academy. He returned to Prague in 1966, and until 1998, he worked in the Institute mainly on archaeological theory and served from 1990 to 1993 as

its director. At the same time, Neustupný was a member of the presidium of the Czechoslovak Academy of Sciences. In 1998, he was the founding director and full professor of the Department of Archaeology at the University of West Bohemia in Pilsen. His specialization is archaeological theory and method, and the prehistory and protohistory of Central Europe ranging from the Neolithic to the Medieval periods.

Neustupný has published five monographs, three edited books, and more than 190 articles. Though his main publications focus on method and theory in archaeology – culminating in his renowned book, *Archaeological Method* (1993) and recently complemented by *Method of Archaeology* (2007) and *Theory of Archaeology* (2010), both not yet translated into English – his broad research interests and output range from studies on relative chronology to radiocarbon dating, from taphonomy to paleodemography, and nutrition through Central European pre- and protohistory. He has been both an active and accomplished field archaeologist – especially during his years at Most, when he spent most of the year in the field and created an effective documentation system for archaeological data from the excavation to laboratory analysis and recording to storage including a pioneering georeferencing of sites in coordinates – and acclaimed connoisseur of material culture, especially that of the Eneolithic period of Central Europe.

Neustupný's archaeological work and research has to be seen in light of the rise and fall of communism in Central and Eastern Europe. His deep conviction and refusal to be manipulated or silenced by its academic leadership is applaudable. On a side note, in the Czech language, *neustupný* means intransigent, unyielding, or pertinacious (Kuna 2012: 3), which quite adequately describes both his personal character and professional work ethic. As a student inspired by Marx, Saussure, and Hegel, he scrutinized the widespread (in continental Europe) culture-historical approach, using similar approaches as the early New Archaeologists/Processualists, such as deductive cognitive models and multivariate methods in mathematical analysis. It is especially interesting that Neustupný – completely isolated from Western archaeological communities – wrote an article on the preservation of bones at prehistoric settlements in the same year (1981) as Binford's famous "Bones" book.

Major Accomplishments

Evžen Neustupný's major accomplishments are in archaeological research and method and theory. He succinctly incorporates these in this writings ranging from *Czechoslovakia before the Slavs* (1961), an internationally acclaimed but in Czechoslovakia heavily criticized outline of the prehistory of this country, which he cowrote with his father, the well-known Czech archaeologist Jiří Neustupný (1905–1981), to his Marxist-inspired book *The beginnings of patriarchy in Central Europe* about the Eneolithic period (1967) and his more recent work on the "*Origin of Megalithic Architecture in Bohemia and Moravia"* (2001). He is also known for his witty, award winning *Antiquity* essay, "Whither Archaeology?" (1971), and his eloquent characterization of paradigm shifts in archaeology. More recently, he has disassociated himself from the processualism which 40 years ago he regarded as the driving force of integration of theory and practice in archaeology (Kuna 2012: 16).

His long-lasting influence on and intellectual struggle with European archaeology is a significant contribution. In particular, his early interest and rigorous support for radiocarbon dating (Bucha and Neustupný 1967) and eventually its calibration not only gained him an invitation to the prestigious Nobel symposium held in Uppsala, Sweden, in 1969 (Neustupný 1970) but also changed our understanding of European prehistory forever. He also coined enduring concepts and theories, such *social landscape* (1998) and lately *artifact archaeology* (2007, 2010), which are widely used both in Continental European and Anglo-American archaeology. His criticism that postmodern/postprocessual archaeologists were so far unable to provide an adequate approach to study the role of the individual as well as events in the past is the basis of a new theory he is currently developing to better understand culture change and culture transfer by rapid transformation of

symbolic cultural systems rather than by vast migration (Kuna 2012: 21–22). In his impressive body of work, Evžen Neustupný has shown that the minority status of Czech archaeology in his division of archaeological communities into mainstreams and minorities might have to be reconsidered.

Neutron Activation Analysis (NAA): Applications in Archaeology

Michael D. Glascock
Archaeometry Laboratory, University of Missouri, Columbia, MO, USA

Introduction

The chemical composition of archaeological materials has long been recognized as occupying an important role to archaeometric studies of technology, provenance, dating, authentication, conservation, preservation, and restoration (Pollard et al. 2007). Archaeologists make use of chemical data on man-made artifacts to investigate the impact of social and economic developments on changes in ancient technology. Compositional analyses of artifacts make it possible for archaeologists to conduct provenance and dating studies and to use the information to develop models of prehistoric migration and exchange (Glascock and Neff 2003). Knowledge of artifact compositions can assist museum curators in determining the authenticity of artifacts and in the development of methods for preserving and protecting

valuable and unique cultural objects (Lister and Renshaw 2004).

One of the important instrumental analytical techniques used to perform chemical analysis of archaeological materials is neutron activation analysis (NAA). The technique was employed to a study of artifacts for the first time during the mid-1950s (see review by Speakman and Glascock 2007). NAA continues, today, to occupy an important role as one of the key analytical methods used to chemically characterize a broad range of artifact types. This entry will explain how the NAA technique works.

Key Issues

Theory Behind Neutron Activation Analysis

NAA is a sensitive multi-element analytical technique used to perform both qualitative and quantitative analysis of major, minor, and trace elements in almost any type of sample (i.e., solid, liquid, or gas). The basis for NAA is that by exposing a sample to neutrons, nuclear reactions are induced with the nuclei of atoms present in the sample. The induced nuclear reactions are followed by the emission of gamma rays that can be detected and their characteristic energies measured to identify the specific nuclear reaction (s) taking place and, hence, identify the elements present in the sample. By measuring the number of emitted gamma rays, the amounts of different elements in the sample can be determined with a high degree of accuracy and precision. For many elements, the sensitivities possible with NAA are at levels ranging into the parts per million, parts per billion, and below. Because it is possible to determine a large number of elements in a wide range of sample types, NAA methods can be used to establish compositional profiles or "chemical fingerprints" of samples to support research in a variety of disciplines ranging from archaeology to zoology (Alfassi 1990).

Readers wanting more information about the theory and practice of NAA and related methods of activation analysis should consult the following references: De Soete et al. (1972), Ehmann and Vance (1991), Glascock (1998), and Neff (2000).

Nuclear Reactions

Nuclear reactions occupy a central role for all methods of activation analysis. In a nuclear reaction, the incident particle interacts with the target nucleus either by scattering or by absorption. The interaction causes the nucleons (i.e., protons and neutrons) present in the nucleus to become excited. The process frequently results in creation of a different product nucleus and the emission of one or more particles and/or photons. The diagram shown in Fig. 1 illustrates a typical nuclear reaction involving interaction of an incident neutron with a target nucleus followed by the emission of both prompt particles and prompt gamma rays and resulting in a new product nucleus. In this example, the latter nucleus happens to be radioactive. Whether or not this new nucleus happens to be radioactive will depend on the nuclear

Neutron Activation Analysis (NAA): Applications in Archaeology, Fig. 1 Sketch showing a nuclear reaction between an incident neutron and a target nucleus. The prompt and delayed emissions that follow from the reaction are also shown. In NAA, the energy and intensity of the delayed gamma signal is measured to determine quantitative composition of the sample

N

properties of the new nuclide. If a radioactive nucleus is produced, the emission of additional decay particles or decay gamma rays will follow through one or more decays until a stable product nucleus is created.

A typical nuclear reaction can be described by the general expression

$$a + A \rightarrow [X] \rightarrow b + B + Q \qquad (1)$$

or in shorthand notation as $A(a,b)B$. In the expression shown here, a indicates the incident particle or radiation, A is the target nucleus, $[X]$ is the compound nucleus in a state of excitation, B is the product nucleus, b is the exiting particle or radiation, and Q accounts for the total amount of energy released or absorbed during the reaction. When Q is positive, the reaction is exoergic. When Q is negative, the reaction is endoergic.

Some of the incident neutron energy is used to conserve momentum for the particle-nucleus system. Therefore, the incident neutron must have a kinetic energy in excess of the Q value. The minimum amount of kinetic energy required for a particular nuclear reaction to take place is known as the minimum threshold energy or E_T.

Most of the reactions used for NAA are exoergic such that the reaction can take place when the incident neutron has a kinetic energy of nearly zero. This is the situation for reactions involving the absorption of thermal or epithermal neutrons. These reactions are also referred to as neutron capture or (n,γ) reactions. At higher neutron energies and when the threshold energy is exceeded, particle-emission reactions such as (n,p), (n,α), (n,n′), and (n,2n) are more common. The diagram shown in Fig. 2 illustrates a portion of the Chart of the Nuclides and shows the positions of product nuclides for selected nuclear reactions relative to the target nucleus.

Most NAA applications rely on measurement of the prompt gamma rays emitted from the compound nucleus $[X]$ or delayed gamma rays emitted from the product radionuclide B. The measurement of delayed gamma rays is usually preferred over measurement of prompt gamma rays because the sensitivities are much higher. The main

Neutron Activation Analysis (NAA): Applications in Archaeology, Fig. 2 Relative locations of the products from various neutron-induced processes on the Chart of the Nuclides. Z is the number of protons and N is the number of neutrons in the nucleus

exceptions are those elements that do not produce a convenient radionuclide (e.g., B, Li, P, Y, Bi, and Pb) for one reason or another. For these elements, it is sometimes necessary to measure the prompt gamma rays or consider use of a completely different analytical method.

Reactor Neutron Spectrum and Reaction Cross Sections

Nuclear reactors based on the fission of uranium offer the most intense neutron sources available for NAA. The neutron spectrum in a reactor consists of three regimes as illustrated in Fig. 3. In the high-energy region, fission-produced neutrons still have most of their original energy (i.e., approximately 2–6 MeV) and are frequently called primary fission or "fast" neutrons. Fast neutrons lose their energy rapidly through elastic scattering with moderating materials in the reactor, such as water and graphite. Neutrons in the energy range from 0.5 eV to 1 MeV are commonly referred to as epithermal neutrons and have been partially slowed down. At energies below 0.5 eV, the neutrons are usually referred to as thermal neutrons, and they have slowed to where they

Neutron Activation Analysis (NAA): Applications in Archaeology, Fig. 3 A typical neutron spectrum from a nuclear fission reactor

have a velocity distribution similar to that of the molecules and atoms in their surroundings. In a typical light-water-moderated reactor, the fluxes of epithermal and fast neutrons are on the order of 2–3% and 6–8%, respectively, of the thermal neutron flux.

The interaction rate for a given nuclear reaction depends on the number of incident neutrons, the number of target nuclei of a particular type present in the target sample, and the probability that the particular nuclear reaction will occur. To a first approximation, the reaction probability, σ, for a single incident neutron is similar in magnitude to the cross-sectional area of the target nucleus, which for most nuclei is on the order of 10^{-24} cm^2. For the sake of convenience, reaction cross sections are usually expressed in units of barns (b), where 1 b = 10^{-24} cm^2. Actual reaction cross sections will vary widely according to the energy and the type of incident particle, the identity of the target nuclide, and the specific type of reaction. In general, neutron capture (n,γ) reactions with low-energy neutrons have the highest cross sections and account for a majority of the radioactivity produced by NAA.

Epithermal neutrons also contribute to the total amount of radioactivity produced by (n,γ) reactions. However, since the number of epithermal neutrons is much smaller, their contribution is usually much less. Due to resonances in the cross-section curve above 0.5 eV, the (n,γ) cross section varies widely. To facilitate the calculation of radioactivity induced by epithermal neutrons, an epithermal cross section (also called the effective resonance integral) is defined by the expression

$$I = \int_{0.5eV}^{\infty} \frac{\sigma(E)}{E} dE \qquad (2)$$

Because both thermal and epithermal neutrons can induce (n,γ) reactions, a non-rigorous but commonly used expression to describe the total reaction rate for a particular nuclide in a uniform flux of incident neutrons is given by

$$R = n\left[\varphi_{th}\sigma_{th} + \varphi_{epi}I\right] \qquad (3)$$

where n represents the number of target atoms belonging to the nuclide of interest in the sample, φ_{th} and φ_{epi} are the respective thermal and epithermal neutron fluxes (cm^{-2} s^{-1}), and σ_{th} and I are the respective thermal and effective resonance integral cross sections (b).

Although reactions involving low-energy neutrons tend to have the highest cross sections, the magnitudes of the cross sections are quite variable and depend greatly upon the target nucleus. At higher neutron energies, the cross sections for (n,γ) reactions are very small. Instead, reactions that result in the ejection from the nucleus of one

N

or more particles – (n,p), (n,α), (n,n′), and (n,2n) – are dominant. As mentioned earlier, these reactions are only possible if the neutron energy is above the minimum threshold energy. Because the energy distribution is complex at high neutron energies, an average cross section for fast neutrons is defined by the expression

$$\overline{\sigma_f} = \frac{\int_{E_T}^{\infty} \sigma(E)\varphi(E)dE}{\int_{E_T}^{\infty} \varphi(E)dE} \tag{4}$$

Using this average cross section, the total reaction rate for a particular fast neutron reaction is given by the equation

$$R = n\varphi_f \overline{\sigma_f} \tag{5}$$

where φ_f is defined as the average fast neutron flux. There are only a few instances in which fast neutrons are important to NAA. Among these are the measurement of nickel using the ^{58}Ni(n,p)^{58}Co reaction and corrections to the (n,γ) reactions for several light-mass elements (e.g., Na, Mg, Al) due to interference from fast neutron reactions. In general, fast neutron reactions range in magnitude from about 0.5 to 10^{-12} b.

For nuclear reactions involving neutrons, the attenuation of neutrons by the sample is usually not a problem because neutrons have no charge and they pass through most samples being analyzed by NAA with very little attenuation. However, the presence of certain high cross-section elements (e.g., boron, cadmium, gadolinium, gold) in a sample can have a significant absorption effect on neutrons causing variations in the neutron flux. This effect is commonly referred to as sample self-shielding. Charged particle beams and photon beams are affected differently from neutrons, such that absorption effects must be considered on the basis of both particle energy and atomic number of the target matrix.

Radioactive Decay

Radioactive decay involves the spontaneous transformation of atoms by emission of particles or gamma rays from the nucleus or by the emission of X-rays after capture of shell electrons by the nucleus. When performing activation analysis, one must recognize the radioactive species, the amount of radioactivity present, and the length of time that the radioactivity will be present. Radioactive decay is a statistical process. For a sample that has been made radioactive, there is no way to predict which atom will be the next to decay, but it is possible to describe the decay characteristics of the entire sample. The number of atoms of a particular radionuclide that decay per unit of time is defined as the activity, **A**, and this rate of decay is known as the fundamental law of radioactivity:

$$A = -\frac{dN}{dt} = \lambda N \tag{6}$$

where N is the number of radioactive atoms and λ is defined as the decay constant. The value of λ is different for each species of radionuclide. The solution to Eq. 6 gives an equation describing the time dependence of the number of atoms of a particular radionuclide present as

$$N(t) = N_0\, e^{-\lambda t} \tag{7}$$

where N_0 is the number of radioactive atoms at time $t = 0$. Therefore, radioactive decay follows the exponential law, and the activity of the radionuclide is controlled by a characteristic property known as the half-life (i.e., the period of time during which half of the original atoms of that nuclide disintegrate). Since the activity is proportional to the number of radioactive atoms, it also decreases exponentially according to the expression:

$$A(t) = A_0\, e^{-\lambda t} \tag{8}$$

The exponential behavior of radioactivity, as defined by Eqs. 5 and 6, is due to the fact that all radioactive transmutations are essentially random. Deviations from this behavior are increasingly smaller as larger numbers of radioactive atoms are monitored.

The half-life is related to the decay constant according to

$$t_{\frac{1}{2}} = \frac{\ln 2}{\lambda} = \frac{0.693}{\lambda} \quad (9)$$

The half-lives of various radionuclides range from milliseconds to several times the age of the universe.

Radionuclide Production

For most NAA measurements, the numbers of nuclei decaying are measured during a post-irradiation time period. The number of decaying nuclei for a particular species depends on the total number of radioactive nuclei produced during the irradiation less the number of nuclei that decayed during the irradiation period and the number that decay during the interval between the end of irradiation and the beginning of measurement. Thus, the rate of production, half-life, length of irradiation (T_i), length of decay (T_d), and length of measurement (T_c) must be considered.

Mathematically, the rate of change in the number of radioactive nuclei during irradiation is given by the difference between rate of production and rate of decay. If one assumes that the sample was irradiated by a uniform flux, an equation to describe the rate of change is

$$\frac{dN^*}{dt} = R - \lambda N^* \quad (10)$$

where R is the reaction rate and N^* is the number of atoms of the radionuclide present. If the Eq. 10 is integrated using the initial condition that $N^*(t = 0)$, then the total number of radioactive nuclei present at the end of irradiation is

$$N_0^* = \frac{R}{\lambda}\left(1 - e^{-\lambda T_i}\right). \quad (11)$$

In general, measurement of radiation emitted from activated samples does not begin immediately after irradiation, but after some period of decay. Under normal conditions, short decay times are used for radionuclides with short half-lives and long decay times are used when the half-life of the radioisotope of interest is long. The long decay time allows possible short-lived nuclides with initially high activities to become insignificant. Therefore, an equation describing the number of radioactive atoms that decay between the start and end of a measuring period is

$$\Delta N = \frac{R}{\lambda}\left(1 - e^{-\lambda T_i}\right)e^{-\lambda T_d}\left(1 - e^{-\lambda T_c}\right) \quad (12)$$

Special Conditions for NAA

When the sample matrix contains high concentrations of Na, Al, K, Sc, Cr, Mn, Fe, or certain other elements with high thermal neutron cross sections, it can be difficult to measure low-concentration elements due to the masking of activities by the major elements. A possible solution for this problem exists for elements that have high ratios of I/σ_{th}. The sensitivities for elements such as Ag, As, Au, Gd, In, Mo, Pd, Pt, Ta, Th, U, and W can be improved by using neutron filters made of B or Cd which themselves have high thermal neutron cross sections to shield samples from thermal neutrons. The technique is known as epithermal neutron activation analysis (ENAA), and by suppressing those elements most sensitive to thermal neutrons, the relative sensitivities for elements with high I/σ_{th} ratios are enhanced. In this same way, the shielded irradiations are also useful for fast neutron activation analysis (FNAA) when the (n,p), (n,α), (n,n'), and (n,2n) reactions are being used to correct for possible interferences with (n,γ) reactions.

Calculating Concentrations

In NAA, the radioactive nuclei produced usually undergo decay to daughter nuclei by emitting beta particles. The daughter nuclei created are often in excited states and undergo emission of one or more gamma rays before arriving at a ground state. In conjunction with the irradiation and decay parameters, measurement of these gamma rays yields the information necessary to determine the abundances of elements in the irradiated sample.

Gamma rays interact with matter in several ways, one of which is an absorption process by which the energy of the gamma ray is transferred to photoelectrons inside a semiconductor detector. The photoelectrons are converted into electrical pulses which can be measured to determine the energy of the incoming gamma ray. A typical

Neutron Activation Analysis (NAA): Applications in Archaeology, Fig. 4 Gamma-ray spectrum from a sample made radioactive by neutron activation

spectrum of gamma rays collected in a high-purity germanium (HPGe) detector used to measure a sample of obsidian after irradiation is shown in Fig. 4.

The photopeaks shown in Fig. 4 are the main gamma rays detected from different radioactive isotopes present in the sample. The actual number of gamma rays collected by the HPGe detector is smaller than the total number of decays due to several factors:

1. The intensities (gamma-ray branching ratios) of emitted gamma rays are in many cases less than 100%. This means that a gamma ray of a particular energy may not be released with every decay event.
2. Some of the emitted gamma rays do not reach the detector. Due to the isotropic nature of gamma-ray emission, only those headed in the direction of the detector can be measured. In addition, absorbing materials between the sample and the detector will reduce the number arriving at the detector.
3. A portion of the gamma rays will pass through the detector without interacting, especially the high-energy gamma rays. In other cases, some gamma rays lose part of their energy through Compton scattering and pair production effects, thus contributing to the gamma continuum beneath the photopeaks of interest.

Peak identification can be accomplished by consulting a number of compilations of decay schemes and related tables listing the associated gamma-ray energies and branching ratios (Erdtmann and Soyka 1979; Firestone et al. 1996). For most peaks, the peak area can be determined by summing the total number of counts under the peak and subtracting an estimated or fitted background. The count rate for a particular gamma ray is then calculated by dividing the peak area by the counting time.

In order to convert the measured count rates into concentrations, one can use an absolute method based on the knowledge of all nuclear and experimental parameters. For NAA measurements using thermal and epithermal neutrons, an equation to express the activity present at any time is

$$A = \left(\frac{m}{M} N_A \theta\right)\left(\varphi_{th}\sigma_{th} + \varphi_{epi} I\right) P_\gamma \varepsilon S D C \quad (13)$$

where m = mass of sample (g), M = atomic weight (g mol^{-1}), N_A = Avogadro's number (6.02×10^{23} molecules mol^{-1}), θ = isotopic abundance, $P\gamma$ = intensity of the measured gamma ray, ε = efficiency of the detector at the energy of the measured gamma ray, S = irradiation factor ($1 - e^{-\lambda Ti}$), D = decay factor ($e^{-\lambda Td}$), and C = count factor ($1 - e^{-\lambda Tc}$).

The absolute activation analysis procedure using Eq. 13 is rarely used in NAA because much easier comparator methods are normally preferred. The equation used to calculate the mass of an element present in an unknown sample relative to a standard with known concentration is

$$\frac{A_{\text{sam}}}{A_{\text{std}}} = \frac{m_{\text{sam}}\left(e^{-\lambda T_d}\right)_{\text{sam}}}{m_{\text{std}}\left(e^{-\lambda T_d}\right)_{\text{std}}} \tag{14}$$

where $A =$ the activity or count rate for the sample (sam) and standard (std), $m =$ mass of the element, and $T_d =$ the decay time. When performing short irradiations, the irradiation, decay, and counting times are usually identical for all samples and standards (i.e., the steps are performed on individual samples and standards sequentially, and all counting uses the same geometry) such that all time-dependent and geometric factors will cancel. Thus, the previous equation simplifies to

$$c_{\text{sam}} = c_{\text{std}} \frac{W_{\text{std}}}{W_{\text{sam}}} \frac{A_{\text{sam}}}{A_{std}} \tag{15}$$

where $c =$ concentrations of the element of interest in the sample and standard, respectively, and $W =$ the weights of the sample and standard.

Standard Reference Materials and Quality Control Monitors

A majority of today's NAA laboratories utilize one or more multi-element calibration standards when performing an analysis. The basic procedure is to collect gamma-ray spectra for both unknowns and standards under conditions that are as similar as possible, then to use one of the equations above to calculate concentrations for the elements whose peaks appear in the gamma spectra of both the standards and the unknowns. Quality control and check standards are usually included with each batch irradiation in order to provide an independent check on the quality of the data and to identify mistakes, such as weighing errors, before the data are interpreted by archaeologists. Certified reference standards for analysis of archaeological and geological materials can be purchased from the National Institute of Standards and Technology (NIST). Other well-known sources of standard reference materials are the United States Geological Survey and the Geological Survey of Japan.

Advantages and Disadvantages of NAA

Neutron activation analysis has a number of important advantages for analysis of many types of archaeological specimens. One of the most important is the transparency of artifact matrices containing high amounts of elements such as C, N, O, and Si. These elements make up the abundance of the sample matrix for a large fraction of archaeological and geological materials; however, by NAA, these elements will hardly form any radioactive isotopes. This makes NAA a more sensitive technique for measuring the trace and minor elements present in solid sample matrices without the need for sample dissolution. Thus, for most types of archaeological samples, it is rarely necessary to perform any sample preparation other than size reduction to obtain an appropriate amount of sample material (usually 100–200 mg is sufficient, but sometimes as little as 5 mg can be used). This limited requirement for sample preparation reduces the likelihood of contamination caused by sample preparation.

Most sources of systematic or random error such as interfering nuclear reactions, overlapping spectral lines, and dead-time losses are readily identifiable, since the theory of NAA is well understood. Nearly all of the interferences that occur can be corrected by adjusting the decay time before measurement or by measuring the same sample twice using different irradiation conditions to correct for fast neutron interferences. Due to its outstanding precision and accuracy, NAA is usually considered the referring technique for samples that yield differing results when analyzed by other analytical techniques.

Neutron activation analysis has some limitations also. Extremely large samples cannot be analyzed in a reactor without making the entire sample radioactive. Therefore, for large artifacts or museum objects, analytical samples must be obtained by removing a piece of the object (e.g., drilling from an obscure location is often recommended). Because NAA usually requires the sample material to be irradiated and measured

following a period of decay, the results are not available immediately. And, in recent years, the number of research reactors has declined such that NAA is gradually becoming less available and the remaining capability is more expensive.

Conclusions

This brief resume has concentrated on describing the basic theory and application of NAA. The method is very sensitive and has a broad range of applications. It is important that users of any analytical methodology understand and recognize the capabilities and limitations of the methods being employed so that accurate and reproducible measurements of major, minor, and trace elements can be performed.

Nevada Test Site

Colleen M. Beck
Desert Research Institute, Las Vegas, NV, USA

Introduction

The Nevada Test Site, now named the Nevada National Security Site due to a change of mission, is located 105 km northwest of Las Vegas and is operated by the US Department of Energy's Nevada Site Office. This test site was the United States continental nuclear testing ground during the Cold War. Between January 20, 1951, and September 23, 1992, the United States conducted 928 nuclear tests there, 100 atmospheric and 828 underground tests (US Department of Energy 2000: xxviii). Other nuclear-related projects also were carried out within the site boundaries, an area of 3520 km^2.

Key Issues/Current Debates/Future Directions/Examples

For many years, archaeological research focused solely on prehistoric and historic cultural

resources, ignoring nuclear testing remains. In 1991, Colleen M. Beck presented a proposal to the Nevada Site Office that outlined the historic importance of the built environment associated with nuclear testing and the need to document these locations. On September 26, 1991, the first nuclear testing-related structure, an underground parking garage designed as a fallout shelter, was studied by an archaeologist and an architect. This research was immediately followed by documentation of the 1527 ft. tall Bare Reactor Experiment Nevada tower, a tower that housed a nuclear reactor used in experiments to accurately estimate the radiation doses received by selected survivors of the atomic bombings of Nagasaki and Hiroshima.

From 1991 forward, the archaeological study of nuclear testing sites has been an integral component of the cultural resources program for the site (Beck 2002). The concept of doing archaeology of Cold War buildings and structures, much less nuclear testing-related locations, was slow to acceptance in the archaeological community. A 1995 article on nuclear testing studies in Archaeology Magazine (Johnson and Beck 1995) generated discussion as to whether or not this work qualified as archaeology and also served as an impetus and example for Cold War archaeological studies related to military installations, government facilities, civilian structures, and at other nuclear facilities within the Department of Energy complex (Schofield et al. 2006; Nickens et al. 2001; Harvey 2001; McGehee 2001).

Between 1991 and the end of 2011, the nuclear archaeology program at the site has documented more than 650 nuclear testing-associated buildings, structures, and objects, as well as artifacts related to the construction and use of testing locations. In the Frenchman Flat historic district (Johnson et al. 2000) and the Apple-2 historic district (Johnson and Edwards 2000), archaeologists recorded the actual structures and features that survived nuclear tests. The Frenchman Flat inventory is noteworthy because no one knew how many nor the types of structures and features left. The archaeological study identified a surprising 157 structures (Fig. 1) and features from 14 atmospheric tests. At the Apple-2 test, one of the wood two-story houses (Fig. 2) still remains, a building type best known from the iconic film footage of the destruction of a similar building by the nuclear blast. One atmospheric test, named Grable, was the only time a nuclear device was shot from a cannon as a nuclear projectile. Although the coordinates of the explosion were documented, the location where the cannon had been placed had been lost through time. An archaeological survey found this place over 10 km south of the detonation. It was identified based on the presence of a trench with substantial

Nevada Test Site, Fig. 1 Nuclear testing remains in Frenchman Flat

Nevada Test Site, Fig. 2 Apple-2 two-story house with blast damage

Nevada Test Site, Fig. 3 Sedan Crater

tie-downs, communication cables, and other assorted artifacts.

In the early 1960s, there were tests associated with the Plowshare Program, a series of projects to evaluate the feasibility of using nuclear detonations for peaceful purposes, such as construction of canals and harbors and to increase oil and gas production. One of these locations, the Sedan Crater (Fig. 3) on the Nevada Test Site is listed on the United States National Register of Historic Places. Archaeologists further identified and documented a number of Plowshare locations in the western United States outside the Nevada Test Site. This research studied locations that had fallen from common knowledge within the Department of Energy after the program ended

Nevada Test Site, Fig. 4 Nuclear testing tunnel entrance

and this work is the only compilation of information on this aspect of the Plowshare Program (Beck et al. 2011).

After 1963, testing was conducted underground in tunnels and vertical shafts. Although craters from nuclear tests in vertical shafts are common, there has been little research conducted at these locations. In recent years, there has been a long-term project to document the historic landscapes of nuclear testing tunnels (Fig. 4) for horizontal underground tests (Drollinger et al. 2011; Jones et al. 2013). Associated landscape features number as many as 200 with a single tunnel. A recent study of structural response program structures, built to study the effect of underground detonations in tunnels and vertical shafts on buildings, provided information about 14 structures that have become enigmas on the landscape.

The sets of benches where dignitaries and others watched the atmospheric tests are a favorite of visitors because everyone tries to imagine what it was like to view a nuclear detonation. Archaeological studies have been completed on News Nob, the best known of the viewing locations and on five other sets at other locations. Three of these sets were first documented through archaeological research.

Archaeological research also has been conducted at other locations related to nuclear research, such as Camp Desert Rock, military trenches, an experimental farm, and the Nuclear Rocket Development Station. At the south end of the test site is Camp Desert Rock, the place where military personnel were stationed during their participation in maneuvers for atmospheric tests. Although all standing structures have been removed, the remains produced a remarkably well-preserved vision of the camp organization. Even trenches near testing locations used by the troops still exist. At the north end was the Environmental Protection Agency experimental farm. Besides a crop field, this farm included a laboratory and dairy facilities for the 100-head herd that was used to determine if radioactive materials in the environment were being transported to humans through the soil-forage-cow-milk food chain. In another area, four facilities at the Nuclear Rocket Development Station present a complex picture of the research and development activities for a nuclear reactor-powered rocket for long trips in space (Drollinger et al. 2000; Beck et al. 2001). A smaller, yet similar facility for the development of nuclear reactor-powered ramjet engines for cruise missiles has also been studied by archaeologists. Rail lines were used to transport the reactors and engines for testing purposes. For years, many of the railroad vehicles, modified for this specialty research, could not be located nor could information about their disposition. Then, it was discovered that most had been stored in an open-

air facility that is now a documented archaeological site.

Future directions in research will develop a methodology to study vertical underground nuclear tests, identify the changes in the cultural landscape based on what is known about the appearance of a test location when it was ready for the detonation, and how the test location looks today. Efforts will continue to document and analyze the nuclear landscape.

Near the test site, archaeologists have been conducting research at a peace camp. This study tells the other side of the nuclear story. Two archaeologists who worked on the Nevada Test Site, Colleen M. Beck and Harold Drollinger, with John Schofield, who had been involved in a peace camp project at Greenham Common in England, began surveying the camp in 2002. Based on a preliminary visit, these archaeologists estimated 50 or so features in the area. Much to their

Nevada Test Site, Fig. 5 Peace Camp symbol

Nevada Test Site, Fig. 6 Rock cairns on hill

surprise, in addition to camping and cooking areas, a Western Shoshone ceremonial space, and some easily seen rock features and geoglyphs, the peace activists expressed their views through a rich artistic tradition that has been left on the landscape. There are geoglyphs of peace signs (Fig. 5), rock circles, sculptures, and drainage tunnels with antinuclear and peace-related paintings and personal expressions. Even the top of a nearby hill is covered with items, such as large rock cairns (Fig. 6), offerings, a stone compass, and a red clay sculpture of a pregnant woman. The discovery of the extensive use of the landscape was not anticipated nor were the more than 800 features that have been recorded there (Schofield et al. 2006; Beck et al. 2007, 2009).

More than 200 antinuclear and peace groups used this area. The largest demonstration was the American Peace Test in 1988 with more than 8000 participants (Butigan 2003). The Peace Camp continues in use today with dozens instead of thousands of people gathering together. The challenge of working at this location has been the changing landscape due to reuse of the area during the research and subsequently, an uncommon aspect to most archaeology that will lead to future recording of new features and alterations to existing features.

Neves, Eduardo Góes

Marcia Bezerra
PPGA/Universidade Federal do Pará/CNPq, Belém, Pará, Brazil

Basic Biographical Information

Eduardo Góes Neves (Fig. 1) was born on March 24, 1966, in São Paulo, Brazil. He has a B.A. in History from the University of São Paulo and a Ph.D. in Archaeology from Indiana University, in the United States. He is the Director of the Laboratory of Tropical Archaeology (ARQUETROP) at the Museum of Archaeology of the University of São Paulo. From 2009 to 2011, he was the President of the Brazilian Archaeological Society. He is a member of numerous international boards in archaeology and anthropology, including the board of the Wenner-Gren Foundation.

Major Accomplishments

Eduardo Neves is part of a group of archaeologists that in the 1990s and 2000s started a movement that revolutionized understandings of the ancient occupation of the Amazon prior to onset of European colonization in the sixteenth century CE (MacEwan et al. 2001). Those archaeologists, including Michael Heckenberger, Stéphen Rostain, Edithe Pereira, Heiko Prümmers, Denise Schaan, Vera Guapindaia, Cristiana Barreto, and Denise Gomes, have produced evidence for dense, sedentary, and long-term occupation in different parts of the Amazon. This evidence challenged the then accepted view that the ancient people of the Amazon had mobile lifestyles in small, unstable, and short-lived settlements. Neves' work seeks to move away from environmental determinism and social evolutionary

typologies to develop new theoretical frameworks to understand the long history of intertwinement between native populations and nature in the wet tropics.

Among Neves' major contributions to archaeology is the systematic study of the nutrient-rich and highly productive *terra preta* soils of the Amazon. *Terras pretas* have been known to naturalists since the late nineteenth century, but it was only 100 years later that geochemical and archaeological research demonstrated that they were created by human management in the past. This recognition brought further data to show that ancient Amazonian have modified their natural settings, presenting a direct challenge to the theory of environmental determinism that dominated Amazonian archaeology through much of the second half of the twentieth century. Neves also did work with Indigenous people of the Amazon such as the *Tukanoan* and *Palikur* Indians (Green et al. 2003), in an attempt to match oral traditions and archaeological data. The results point to a remarkable fit between these different sources of data and show that these Indigenous people have occupied their current areas continuously for many centuries.

In 1995 Eduardo Neves, together with Michael Heckenberger and James Petersen, started the Central Amazon Project (CAP), which Neves led until 2010. Petersen's untimely and unfortunate death in 2005, when he was shot in a robbery at a roadside restaurant during fieldwork, was a major blow to everyone involved in that long-term research effort. Indeed, Petersen's loss was felt not only by those with whom he worked in the Amazon but also among his colleagues and students from the Caribbean and New England, in the United States.

The Central Amazon Project is the longest-running project held in Amazonian archaeology. It has included the careful and intense mapping of dozens of the large archaeological sites located around the area of confluence of the Amazon and Negro rivers in Brazil, the establishment of a regional chronology and interdisciplinary research. However, its major contribution probably comes from the fact that it provided a venue for younger archaeologists, Brazilian and foreign, to obtain their graduate and undergraduate training in Amazonian archaeology. This was done through field schools held annually and also through the graduate program in archaeology at the University of São Paulo, in collaboration with other institutions such as Cambridge University, the University of California at Berkeley, Kansas University, the French National Museum of Natural History, and the Brazilian National Museum.

Neves has also made a major contribution to the development of robust theory in South American archaeology through his work, together with Pedro Funari, in the conception and inception of the "South American Theoretical Archaeological Meetings" (TAAS), which they initiated at the city of Vitória, Brazil, in 1998. Since that time, TAAS meetings have been held regularly, on average every 3 years, in different South American countries such as Argentina, Colombia, and Venezuela. Over the years TAAS meetings, which are self-regulatory and unattached to any archaeological association, have provided an opportunity for South American archaeologists to meet and discuss topics related to the history and political dimension of the practice of archaeology in the continent.

Aside from research and teaching, Eduardo Neves has played a major part in the development of a framework for the practice of professional archaeology in Brazil. He has trained and supervised a host of young archaeologists which are active in Amazonian research and currently work and teach at different local universities and research institutions. He has designed and helped to create the undergraduate program in archaeology at the State University of Amazonas and is continuously engaged into widening the possibilities for the socially conscious practice of archaeology in the Amazon.

"New 7 Wonders of the World" Campaign

Helaine Silverman
Department of Anthropology, University of Illinois at Urbana-Champaign, Urbana, IL, USA

Brief Definition of the Topic

The "Seven Wonders of the Ancient World" are well known to anyone who has had a Western-style high school education. They were located around the Mediterranean and Fertile Crescent. The list of these monuments was the result of peripatetic Hellenic colonization and early tourism. The best known of the Greek lists was made in the first half of the second century BCE by Antipater of Sidon. The most commonly cited ancient seven wonders were: Pyramids of Giza, Hanging Gardens of Babylon, Temple of Artemis at Ephesus, statue of Zeus at Olympia, Mausoleum of Halicarnassus, Colossus of Rhodes, and Lighthouse of Alexandria.

Two thousand years later, in 2001, Canadian-Swiss Bernard Weber created the "New Seven Wonders of the World Foundation" (N7WF) and launched a worldwide competition to create a new list. Countries were invited to nominate their sites and to encourage their citizens to vote for the "wonders." The winners were announced on 7 July 2007 in Lisbon. The N7WF claimed that some 100 million votes had been cast. The winners were Chichen Itza, Colosseum of Rome, Machu Picchu, Great Wall of China, Petra, Taj Mahal, and the non-ancient Christ Redeemer Statue overlooking Río de Janeiro. The reason for including this campaign in the *Encyclopedia of Global Archaeology* is because of the challenge the N7WF presented to UNESCO's own World Heritage List and because the campaign itself showed the tight relationship between national archaeological patrimonies, coveted international prestige, and the global tourism industry.

UNESCO stated on 20 June 2007 (before the results of the contest were known): "There is no comparison between Mr. Weber's mediatised campaign and the scientific and educational work resulting from the inscription of sites on UNESCO's World Heritage List. The list of the '7 New Wonders of the World' will be the result of a private undertaking, reflecting only the opinions of those with access to the Internet and not the entire world. This initiative cannot, in any significant and sustainable manner, contribute to the preservation of sites elected by this public" (UNESCO 2007).

UNESCO's attitude is hypocritical, given the severe criticism that has been directed at its World Heritage Committee in recent years over its politicization and the lack of transparency of its decision-making and because the driving force behind countries' nominations is rarely site preservation but rather national pride, international recognition, and potential marketing of a new tourist attraction. UNESCO provides little money for site preservation and, as its own List quickly approaches one thousand inscriptions, one must consider that the N7W popular poll has selected six (not the Christ the Redeemer Statue) truly spectacular and significant sites that do meet the UNESCO criteria for "outstanding universal value" (see http://www.culture.gov.uk/images/consultations/UNESCO10_criteria.pdf).

In contrast to UNESCO's monopolization of cultural heritage authority, the United Nations praised the N7W campaign as part of its "Millennium Development Goals." On 8 July 2007, the United Nations Office of Partnerships lauded the campaign, noting its "aim to contribute to the process of uplifting the well being and mutual respect of citizens around the world, through encouraging interaction, expression of opinion and direct participation by voting and polling on popular themes and global issues which are understandable to everyone" (United Nations 2007).

State of Knowledge and Current Debates

Introduction

"When he goes out in the open, he not only keenly observes the activities of people and their consequences in the material world but also seeks to recognize patterns in both and link these together." This is a comment about recently deceased Lewis Binford, the principal proponent of New Archaeology, which the author heard during his tenure as a Fulbright Senior Research Fellow at the University of New Mexico, Albuquerque, in 1987 from one of the doctoral students there. It captures equally well the whole message of New Archaeology. The defining features of New Archaeology are as follows:

1. Emphasis on the recognition of interrelationships among various units of the archaeological record
2. Adoption of scientific reasoning for isolating causative factors that enable us to infer human behavior from these linkages
3. Imparting an overall anthropological dimension to the discipline by way of making the explanation of cultural similarities and differences across time and space as its primary goal

These are now firmly entrenched in the fabric of contemporary archaeology.

This entry investigates the following major aspects of New Archaeology: (a) the overall academic ferment that prevailed in social sciences in the mid-twentieth century; (b) how it facilitated or even anticipated the growth of a nonconformist movement in archaeology; (c) reconceptualization of theoretical and methodological domains of the whole discipline; (d) growth of sub-schools within New Archaeology; (e) some examples of field research from both New and Old Worlds involving the application of New Archaeology's formulations in theory and method; and (f) the place of New Archaeology in the context of later developments in the discipline.

Background

Far from constituting an aberration, the rise of New Archaeology fits in very well with our knowledge of the history of major developments in both the natural and social sciences, each one continuously striving to achieve a more systematic and comprehensive understanding of the whats, wheres, whens, hows, and whys of a specific portion of the empirical world forming its

subject matter. One general feature that strikes us is that all these disciplines were initially preoccupied with singular-atomistic studies, which were subsequently replaced by perspectives treating phenomena as *Ganzheiten* or interconnected wholes.

Secondly, in their formative stages, these sciences primarily concerned themselves with the identification of broad, long-term trends about their respective domains of the empirical world. Soon a need was felt to put these sweeping ideas on a sounder basis by taking up systematic studies of spatially and temporally limited portions of reality. In the physical sciences, experimental method played an important part in these fresh studies from the beginning of the eighteenth century. Commenting on its role, Heisenberg (1952: 79) wrote: "This method could be applied to individual problems posed by nature and hence it was no longer a question of understanding a single interconnected whole but of a detailed analysis of many small specific connections." Highlighting a similar situation that prevailed in the social sciences, the nineteenth-century French sociologist-philosopher Tarde averred: ". . .a new science begins by assuming the existence of large-scale "apparent" regularities, but can genuinely advance only with the discovery of the real, small-scale repetitions" (as quoted by Martindale 1961: 446).

It was against this wider background that many of the social sciences took new incarnations towards the end of the nineteenth century and in the first half of the next century. New Geography, New History, New Sociology, New Anthropology, New Political Science, etc. appeared on the academic horizon.

In its antiquarian stages, archaeology too was concerned with particular sites and monuments and then started recognizing broad, long-term trends in the preliterate past of humankind. C.J. Thomsen's Three-Age system – Stone, Bronze, and Iron Ages – was the first step in this direction (Thomsen 1848). These ages were much elaborated and improved upon in the second half of the nineteenth century by John Lubbock and many other workers in Europe. Benefiting from the recognition of these stages and also from the archaeological discoveries made in the first half of the twentieth century, several evolutionary or developmental models of the preliterate stage were put forward. Publications such as Gordon Childe's *Man Makes Himself* (1936) and *What Happened in History* (1942) and Leslie White's *The Evolution of Culture: The Development of Civilization to the Fall of Rome* (1959) not only strengthened the discipline's academic identity and brought the story of humankind to the threshold of the educated layperson but also gave a fillip to regional archaeological investigations in both Old and New Worlds. Thus, culture history, involving the preparation of regional timetables of culture, emerged as a dominant trend by the mid-twentieth century.

Cultures were defined as recurrent series of similar-looking artifactual assemblages having spatiotemporal boundaries. The introduction of various scientific techniques and methods after World War II added an extra dimension to the study of the archaeological record (Brothwell and Higgs 1963). Wherever large-scale excavations were undertaken, it was even possible to say something about the past lifeways. In short, lots of queries about the whats, whens, and wheres of the archaeological record were raised and successfully answered. Soon some books devoted to theory and method also appeared, e.g., Grahame Clark's *Archaeology and Society* (1939), Gordon Childe's *Piecing Together the Past* (1956), Willey and Phillips's *Method and Theory in American Archaeology* (1958), and Stuart Piggott's *Approach to Archaeology* (1959).

These positive developments, while they constituted what David Clarke (1973) called the stage of self-consciousness, were not without their skeptics. Clarke (1968: xiii) himself called the whole endeavor "an undisciplined empirical discipline." The issue for the discipline was epistemological in nature and necessitated a reexamination of its foundations and a logical analysis of its concepts. In other words, questions were raised about the quality of knowledge itself about the past. Could one elevate this knowledge from the level of data-packed, inductive generalizations or assortments of facts to that of seeking interconnections among these facts? Observations

like the one made by the French filmmaker Louis Renoir that "I care not for things themselves but their interconnections" began to find an echo in archaeological circles too. Gordon Childe (1935) and John Bennett (1943) called attention to reading the meanings of the archaeological record in functional terms. In his Rickett Memorial Lecture of 1953, Grahame Clark diagrammatically represented human culture as made up of various structural components, all linked one with another and with the environment (Clark 1960: 175). Walter Taylor's (1948) book *A Study of Archaeology* not only advocated contextual and functional approaches to the analysis of archaeological data but in fact anticipated the more recent interpretive trends by locating the source of behavior in human minds and the various feelings and sentiments generated there. Julian Steward's (1955) cultural ecology stressed the need for monitoring interconnections between cultural and environmental components, while Willey and Phillips (1958) called for an anthropological orientation to the whole discipline.

But all these views and ideas were in the form of isolated pleas for improvement and therefore failed to make any significant impact on the archaeological community. It was left to the proponents of New Archaeology to coalesce these "germs of thought" and add to these the hardware as formed by statistical techniques for pattern recognition and the software as provided by principles of the scientific method. Once this fusion took place, a virtual manifesto was born, as contained in the initial writings of Lewis Binford (1962, 1964, 1965, 1968a) and David Clarke (1968, 1973). One is reminded here of the analogy provided by the famous pamphlet of 1929 issued by the Vienna Circle, which wanted to free empirical sciences from the "metaphysical and theological debris of millennia" and inject into these a scientific world conception (wissenschaftliche Auffassung) (Hahn et al. 1929). Archaeology simply represents the latest example among empirical sciences which experienced this shift from a mere concern with bundles of facts to the construction of positivist and verifiable knowledge about the real world. It is unimaginable that without the background provided by this fundamental change, the ideational trends that later arrived in archaeology would have found a rationale for their genesis.

Birth of New Archaeology

The actual genesis of New Archaeology took place in the 1960s. Not many feathers will be ruffled when it is said that the *dramatis personae* comprise just two figures – David Clarke from England and Lewis Binford from the USA. Let us first consider the views of Clarke. He introduced statistical methods to understand variability in the archaeological record, be they simple artifacts or megalithic tombs. By means of matrix analysis, Clarke recognized two main geographical or functional series within the British Beaker pottery dated to the third millennium B.C. (Clarke 1962). In 1968 he published his book *Analytical Archaeology*, which sought to revamp the whole conceptual framework of the discipline. Of particular importance is his conception of cultures as systems consisting of components interacting among themselves and with the environmental subsystems. His paper "Archaeology: The Loss of Innocence" was a terse (hence termed gobbledygook by readers in Britain) but welcome exposition of the major tenets of the new stream of thought (Clarke 1973). He identified four stages in the development of archaeology, viz., stages of consciousness, self-consciousness, critical self-consciousness, and self-critical self-consciousness. He also advocated the study and interpretation of the archaeological record with reference to four paradigms (geographical, anthropological, morphological, and ecological). Clarke visualized that the application of these four paradigms would lead to improvements in theory formation at four levels: concepts, information, reasoning, and general theory. These views surely reflect Clarke's larger conception of the archaeological record in cultural and anthropological terms. Finally, he defined New Archaeology as "an interpenetrating set of new methods, new observations, new paradigms, new philosophies and new ideologies within a new environment" (Clarke 1973: 12). His death in 1976 at the young age of 38 robbed archaeology of one of its most fertile minds.

Binford's contribution to the emergence of New Archaeology was as much an expression of mind inspired by ideas about the relevance of scientific reasoning and statistical techniques for pattern recognition as it was the product of clashes of ideas with senior colleagues like James Griffin and Robert Braidwood at the universities of Michigan and Chicago about the nature of the archaeological record and its potentialities to inform us about the past. The introductory portions of the three volumes containing his collected essays (Binford 1972a, 1983a, 1989) and also the inside view provided by one of his group members (Flannery 2006) provide many gripping details of the birth pangs as well as of later developments concerning New Archaeology's efforts to direct attention to the larger anthropological goals of the discipline (Willey and Sabloff 1980: 181–210; O'Brien et al. 2005: 36–66). Binford (1972: 1–14) told us how his stint of military service in East Asia created in him an interest in observing simple societies, this in turn motivating him to enroll for a graduate program in anthropology, and how he developed "archaeology commitment" in order to provide a temporal perspective for explaining diversity in human societies across the globe. He also told us about the clashes he had with senior archaeologists about the very definition of concepts like culture, the whys and hows of the emergence of food-producing way of life, and explanation of variability in archaeological record. So it fell upon Binford to play the role of a Darwin as well as that of a Huxley.

The Structure of New Archaeology

With this background we shall now identify the main propositions of New Archaeology. It should be noted at this stage that the phrase New Archaeology was a pejorative expression used by critics for lumping together unconventional papers that were being presented by Binford and his group at meetings of the Society for American Archaeology in the early 1960s. Binford himself was content with characterizing the views of his group as "New Perspectives" that call for "some fundamental changes in the way archaeologists viewed the archaeological record and particularly in the conventions then current for assigning meaning to archaeological facts" (Binford 1986: 459). But the label got entrenched in the literature.

Conceptual Changes

New Archaeology argued for a basic epistemological change. In traditional archaeology, facts per se – be these about dates, sizes of sites, or the actual finds – constituted knowledge and were regarded as self-explanatory. These were only required to be organized into assortments or groups. Generalizations in the form of summaries of facts constituted knowledge about the past, e.g., culture X has red and grey ceramic fabrics in equal proportions, represented by 13 and 16 vessel shapes, respectively. New Archaeology raised doubts about the limitations of this form of knowledge in promoting the cause of anthropological orientation to archaeological record. As Bertrand Russell would have argued, can we meaningfully understand the world around us by merely enumerating its "furniture?" The anthropological dimension, involving the study of development of human cultural forms along space and time trajectories, required the archaeologists to thread their facts together. Adopting the age-old saying "Divided we fall, united we stand," the new epistemological turn laid emphasis on linkages among facts.

This epistemological reorientation entailed two drastic changes in the culture concept. First, in the place of the earlier "shreds and patches" and trait list versions, cultures now began to be treated as totalities or systems comprising not merely component elements but their interrelationships as well. Secondly, the normative definition of culture as a repository of ideas and norms held in the minds of people was now substituted by a functional definition treating it as an extrasomatic means of adaptation. Butzer (1982) independently discussed at length the operational strategies required for putting the concept of adaptation to use. This redefinition of culture highlighted the study of culture process, which has become synonymous with New Archaeology.

In order to emphasize the importance of anthropological orientation to the discipline advocated by him, in the initial stages, Binford did talk of archaeology's contribution to the

understanding of diachronic or long-term trends in the evolution of culture and even referred to tracking down "laws of cultural dynamics." But it was soon realized that this task must be preceded by a more fundamental task, i.e., holistic understanding of spatially and temporally limited segments of the archaeological record. This required a shift of emphasis from the study of culture of humankind to the investigation of cultures of peoples. It is the study of this synchronic aspect of culture which constitutes culture process; it finds expression at numerous places in the writings of both Clarke and Binford. Their views were influenced by systems framework and the ecosystem approach which had just emerged as prominent analytical tools in the empirical sciences.

A few additional remarks are warranted on this specific issue. David Clarke (1968: Chaps. 2 and 3) viewed archaeological cultures as vast information systems, made up of several interlinked subsystems. He viewed the aim of archaeology as the identification of patterns or regularities in the functioning of cultural systems, which in turn would lead to a higher body of knowledge in the form of models and hypotheses. Binford espoused the culture process concept in more elaborate terms.

Writing in 1968, Binford stated: "Process, as I understand it, refers to the dynamic relationships (causes and effects) operative among the components of a system or between systemic components and the environment" (Binford 1972a: 117). Some years later, he warned that "A cultural system is not a summation of all the events, behaviours or other transactional phenomena going on at a given time, but rather the conditioning organizational framework within which all these events transpire" (Binford 1981a: 201). Later, Binford underlined the priority of the study of process at a synchronic level in these words: "...before archaeologists could cite formal variability in the archaeological record as indicative of large-scale process, evolution, system changes, ethnicity, or even such historical events as migrations, we had to be able to recognize the archaeological record at differing organizational scales" (Binford 1989: 18).

Thus, in their advocacy of the cause of culture process, neither Clarke nor Binford showed any interest in producing yet another grand model of cultural evolution. Rather their interest was in "freezing" cultural systems in space and time in order to understand their functioning. This synchronic process orientation of New Archaeology was influenced by the prevailing functionalist trends in anthropology via the writings of Leslie White and others. As stated earlier, it constitutes a major instance of the operation of two important trends noticed in the history of factual sciences. These are as follows: (a) a coming into vogue of theories treating phenomena as *Ganzheiten* in replacement of singular-atomistic studies and (b) a shift of emphasis from the formulation of linear or long-term trends to the detection of constant, short-term relationships, and uniformities. It is worth noting here that processual orientation to the study of social phenomena was already a prominent feature of the American social sciences like sociology, political science, and economics in the early part of the twentieth century (Kress 1970).

Methodological Innovations

To give effect to these radical conceptual changes, New Archaeology proposed innovations in the methodological approaches or strategies to be adopted for studying the archaeological record at various levels. Realizing that cultural systems of whatever age always operate at a regional level but never exclusively at the level of individual sites – however big these might be, a Cahokia or a Troy or Harappa – Binford called for the employment of a regional research strategy in field investigations. In his own words, he said: "It is argued that the methodology most appropriate to the study of culture process is a regional approach in which we attempt to gain reliable and representative information covering the internal structure and ecological systems" (Binford 1964: 160). The archaeological record was now visualized as consisting of populations of cultural items, cultural features, sites, and ecofacts or non-artifactual data of cultural significance. Since it is not always possible to exhaustively study all

portions or aspects of regional or site data, New Archaeology for the first time introduced probability sampling methods and multistage fieldwork into the discipline for identifying and studying representative units of data universe.

As a complement to these innovations in field strategies, New Archaeology also called for a more rigorous analysis of the archaeological record itself. Reference has already been made to Clarke's use of matrix analysis for restudying British Beaker pottery. Under Albert Spaulding's tutelage, Binford acquired familiarity with multivariate statistical techniques which proved to be extremely helpful to him in identifying patterns in the archaeological record and also in inferring similarities and differences among cultural systems.

These innovations in field methodology and data analysis were pooled together by Binford to develop a research paradigm called the settlement system approach (Binford and Binford 1969). While settlement pattern studies stop at the level of descriptive accounts of distribution of sites on a given patch of landscape (Willey 1953; Chang 1968), the settlement system approach is explanatory in nature and seeks to lay bare the linkages between site contexts, resource use schedules, demographic arrangement, and ecological setting. While neighboring human groups may share similar genetic, linguistic, and historical traditions, they nevertheless tend to develop their own settlement systems due to differences in both natural and social environments. Initially, the settlement system approach was developed by Binford to explain variability in the French Mousterian assemblages. This work and his prolonged ethnoarchaeological study of the Nunamiut Eskimos of Alaska enabled him to formulate the forager versus collector model of hunter-gatherer settlement systems (Binford 1980). His more recent book *Constructing Frames of References: An Analytical Method for Archaeological Theory Building* (2001) extended this model to cover all major hunter-gatherer societies spread across the world. With some additions and variations, it is also applicable to the study of food-producing and other developed cultural systems.

The Role of Scientific Reasoning

There are two important and overarching aspects of New Archaeology – both falling within the domain of scientific reasoning (Paddayya 1983, 1990: 8–19). One of these concerns the nature and role of laws or generalizations in archaeological research. This topic generated much debate in the discipline and to some extent even scandalized New Archaeology by caricaturing its proponents as "a law and order group." During his visit to one of the universities in Midwest America in 1999, the author noticed on the doorway of a senior faculty member this short inscription: "All generalizations are false." This hostile attitude to the topic was occasioned by certain misconceptions: (a) traditional archaeology's relativistic and trait list conceptions of human cultures, providing no scope for generalizations; (b) the supposedly inviolable nature of lawlike propositions in the natural sciences; and (c) the unwarranted view that laws in archaeology must refer to long-term trends in human culture.

Such misconceptions are totally uncalled for on various counts. First, laws do not exist in nature but are conventions made by us to designate recurring patterns or associations (causal and otherwise) among phenomena. Secondly, there is no finality attached to them, since the empirical world is infinite and new data could necessitate revision or even discard of existing generalizations. So the inscription on the doorway of the American professor should more appropriately read: "All generalizations are false and are liable to be replaced by newer ones." Thirdly, generalizations are not ends in themselves but form "an indispensable instrument of historical research" (Hempel 1965: 231). Mandelbaum (1977) aptly called them the "mortar" of historical accounts. Fourthly, the oft-repeated dichotomy that sociocultural sciences are idiographic (seekers of individual facts) and that natural sciences are nomothetic or lawmaking is totally false. The fact is that research in all empirical sciences presupposes an unending cycle between acquisition of facts and threading them together with the help of generalizations. Hence, both groups of sciences are idiographic as well as nomothetic. There is absolutely no way that

archaeology can be excluded from this matrix and accorded a special status.

As pointed out by Hempel (1965: 242–243), past-related sciences like history and archaeology do make use of prescientific generalizations of everyday experience as well as generalizations adopted from both social and natural sciences. Archaeology has made its own generalizations, e.g., Three-Age system, law of evolutionary potential, and law of cultural dominance (Stickel and Chartkoff 1973).

Middle Range Theory, as developed by Lewis Binford, seeks to identify more of such general propositions (Arnold III 2003). It rises above the earlier arbitrary ways of giving meanings to the archaeological record and aims to develop a fresh cognitive frame of reference. This cognitive framework consists of ideas and concepts in terms of which one could diagnose the archaeological record in order to identify the processes that led to its formation (Binford 1977, 1981a). Binford visualized that Middle Range Theory (encompassing ethnoarchaeological research, use-wear analyses, and bone taphonomy) could produce patterns at three levels: (a) first-order field or laboratory observations about various segments of the archaeological record, (b) second-order observations recognizing patterns between two or more variables, and (c) pattern recognition leading to theory formation which establishes causal links in cultural systems and explains their functioning. Middle Range Theory paves the way for General Theory which has the task of "understanding the processes responsible for change and diversification in the organizational properties of living systems" (Binford 1977: 7).

Binford's book *Constructing Frames of Reference: An Analytical Method for Archaeological Theory Building* (2001) contains a large number of lower-, middle-, and higher-order generalizations arrived at after a comparative study of 340 hunter-gatherer societies of the world. Referring to their possible use to archaeologists, Binford (2001: 3) writes: "...From the equations developed in the book an archaeologist can anticipate many of the properties of hunter-gatherer groups that might be expected to occur at a given location, at an archaeological site or at a series of sites...the explanatory theory is available for archaeologists to use deductively by reasoning to or simulating changing conditions and thereby providing patterns of change that can be expected to occur in the archaeological record at specific locations...."

Another major contribution made by New Archaeology to the discipline relates to the introduction of the method of hypothesis testing. Traditional archaeology was mainly based on the use of intuitive and ex cathedra statements. Attention was now focused on the need to test the reliability of archaeological reconstructions. For this purpose the method of the hypothesis-forming part of the philosophy of science was adopted. In Binford's own words, "The accuracy of our knowledge of the past can be measured; it is this assertion which most sharply differentiates the new perspectives from more traditional approaches. The yardstick of measurement is the degree to which propositions about the past can be confirmed or refuted through hypothesis-testing" (Binford 1972a: 90). Although one could locate some instances of hypothesis formulation in traditional archaeology, e.g., Thomsen calling his Three-Age system a conjecture to be confirmed or rejected in the light of future work and the Iraq Jarmo project of Robert Braidwood (1974) for ascertaining Neolithic origins, New Archaeology's culture process goals called for a formal introduction of the hypothetico-deductive method in order to deal with the problems of the whys and hows of culture process. It involves putting forward a hypothetical answer to a problematic situation concerning the archaeological record and deducing from it consequences which could be tested with reference to the empirical world. In the natural sciences, the application of this method led to far-reaching qualitative changes in knowledge formation.

As with the topic of laws, the method of hypothesis too invited much doubt and disbelief in archaeology in the initial stages. The reason was that traditional archaeology had by and large been content with answering questions of what, when, and where by making inductive statements taking the form of summaries of facts. The scope for raising why and how queries was limited. Moreover, it was mistakenly believed that

hypotheses should always involve "if, then" causal links. The truth is that research in empirical sciences has much scope for and needs non-causal hypotheses too. The Greek philosopher Novalis put this issue very well: "Hypotheses are like nets; only he who casts, will catch" (Popper 1980: 11). In our own times, the French scientist Poincare tendered this useful advice: "Instead of summary condemnation we should examine with the utmost care the role of hypothesis; we shall then recognize not only that it is necessary, but that in most cases it is legitimate. We shall also see that there are several kinds of hypotheses; that some are verifiable, and when once confirmed by experiment become truths of great fertility; that others may be useful to us in fixing our ideas, and finally, that others are hypotheses only in appearance, and reduce to definitions or to conventions in disguise" (as quoted in Copi and Gould 1972: 284).

Aftermath

Estimates of the place of New Archaeology vary. James Griffin (1985) observed total silence about it while reviewing his career achievements in archaeology. Walter Taylor (1972) called these ideas "old wine in new skins." In contrast to this opinion, another senior archaeologist Paul Martin (1972) called it a revolution. But this has been denied by Meltzer (1979); he believes that it represents a continuum with traditional perspectives.

Revolution or not, New Archaeology represents a set of eclectic conceptual and methodological tenets aimed at a reorientation of our basic perceptions of the archaeological record. The following are the principal new perceptions:

(a) Systemic conception of cultures in the place of the traditional type-fossil and trait list views
(b) Emphasis on knowing how cultures function with reference to their own components as well as surrounding environmental and social milieu
(c) Adoption of a regional perspective in field studies
(d) Use of various pattern recognition techniques
(e) Emphasis on the use of generalizations secured via Middle Range Theory
(f) Application of the method of hypothesis

All these were geared to raise knowledge of the past from the level of accumulation of individual facts to the status of science that seeks to identify their interconnections and explain their whys and hows (Wylie 1981; Watson 1991; Gamble 1999; Meltzer 2011). New Archaeology thus achieved the effect of the "lowering of foundations" of the discipline and brought in a new paradigm in the sense of "a universally recognized scientific achievement that for a time provides model problems and solutions to a community of practitioners" (Kuhn 1962: x).

New Archaeology failed to remain a unified stream of thought. Influenced or inspired by it in one way or another, several "newer" archaeologies appeared on the American scene from the 1970s onwards. These include an "explicitly scientific" archaeology (Watson et al. 1971), the behavioral archaeology of Michael Schiffer, cultural materialism (Segraves 1974), Marxist archaeologies (Spriggs 1984), critical archaeology (Leone et al. 1987), Annales perspectives (Knapp 1992), cognitive processual archaeology (Renfrew 1994), and evolutionary archaeologies (Maschner 1996; O'Brien and Lyman 2000). While no doubt conceding the importance of processual orientation provided to the discipline by New Archaeology and also its efforts to strengthen the discipline's conceptual foundations, these perspectives seek to attend to some of the gaps left untouched by the main program.

Among these behavioral archaeology, as developed by Michael Schiffer, is a more prominent and enduring one. Schiffer successfully argued that inferring human behavior from the archaeological record entails us to first recognize the processes involved in the transformation of objects from one state to another within the original systemic or living context and then their transfer to the archaeological context (Schiffer 1976). He also pointed out that archaeologists paid no attention to the possible cultural as well as natural processes that acted upon the archaeological record since its disconnection with its creators. Thus, Schiffer highlighted for the first time the need to understand the processes that create as well as transform the archaeological record before we use it for reconstructing past human behavior

(Schiffer 1995). It is not surprising therefore that the topic of formation processes (*c*-transforms and *n*-transforms) has become an integral component of contemporary archaeology's suite of research strategies (Schiffer 1987).

Impact

Let us briefly consider the impact made by New Archaeology on the discipline. Its theoretical and methodological propositions made sense particularly to those who were actively involved in the study of the archaeological record in the field or laboratory and who desired to pull out interconnections of various kinds from the "teeth of stubborn and irresistible" facts. Citation of a few studies carried out at site or regional levels will serve the purpose of this encyclopedic entry. Let us start with the two architects themselves.

Two of David Clarke's reinterpretations of the European archaeological record are fascinating examples of model building. First, we will consider his restudy of the archaeological record of the British Iron Age site of Glastonbury excavated three quarters of a century ago. His efforts to infer "mutual relationships and the strengths and covariation of those relationships in a variety of alternative classificatory dimensions" led him to slot this small Iron Age site at a lower level of the four-tier settlement (and impliedly social) hierarchy that existed in the marshlands of Somerset (Clarke 1972). The second study concerns the nature of economic organization of the North European Mesolithic phase. Clarke carefully examined the functional aspect of microlithic assemblages and implications of the spurt in vegetative growth consequent upon the retreat of ice sheets from North European plains. This led him to doubt the traditional emphasis on hunting. Instead he proposed the view that the Mesolithic subsistence economy "may have approached limited, fire-controlled asexual horticulture and arboriculture, based on vegetatively reproducing *root* staples, forest *perennials*, controlled nut and fruit trees, backed up by shell-fish, dog and pig husbandry. . ." (Clarke 1978: 36).

Binford's first major use of the new armature for approaching the archaeological record concerned the four or five variants that had been recognized by Francois Bordes within the French Mousterian. Raising serious objections to Bordes' interpretations equating the variants with different ethnic groups, he and his wife Sally Binford put forward the famous functional argument which sought to trace assemblage variability to functional variability, which in turn is governed by seasonal variability in the availability of resources (Binford and Binford 1966). This argument was extended to account for variability in the Late Acheulian assemblages from Olorgesailie, Kalambo Falls, and other sites in Africa (Binford 1972b). Later Binford used this strategy and reexamined the faunal collections obtained much earlier from Olduvai Gorge localities in East Africa from the point of view of bone taphonomy and arrived at the startling conclusion that the early hominins, far from being great hunters, were only scavengers of the leftovers of meat from carnivore kill sites (Binford 1981b, 1983b). Likewise the mighty "elephant hunters" of Torralba were reduced to the status of mere expedient exploiters of animal food resources naturally available in the ecosystem (Binford 1987). These studies provided much stimulus to contemporary research on bone taphonomy and hominin dietary patterns.

Likewise, in his paper "Post-Pleistocene Adaptations," Binford (1968b) reviewed evidence pertaining to origins of food-producing ways of life. Going beyond "nuclear zone" and "culture was ripe" theories, he put forward the view that in the Near East evidence of plant and animal domestication at the primary level would be found not in the areas occupied by sedentary forager-fisher groups but in the adjacent zones. He further pointed out that evidence for independent experiments in food production could be expected from various areas in both New and Old Worlds – a proposition upheld by a series of field projects undertaken subsequently.

The Mousterian debate with Bordes made Binford realize the need to supplement archaeological data with analogies arising from the study of the actual functioning of living hunter-gatherer societies. His 4-year-long (1969–1973) field studies among the Nunamiut Eskimos of Alaska and the resulting publication set a model for later work

in hunter-gatherer ethnoarchaeology (Binford 1978). It has already been mentioned that the settlement system approach to the archaeological record developed by him is a lasting contribution to the discipline and, with suitable modifications and additions, is helpful for studying the structure and functioning of even agropastoral and other later cultures.

We will now examine the use of new ideas by other archaeologists. The volume *New Perspectives in Archaeology*, edited by Sally and Lewis Binford (1968), contains a set of ten papers presented at a symposium organized in Denver in 1965 as part of the annual conference of the American Anthropological Association. These papers represent the first-generation applications of New Archaeology in the Americas. Irven DeVore, one of the seven leading non-archaeological anthropologists of the time who had been invited to comment on these papers, summed up the overall positive response in these words: "...I warmly applaud the shift in emphasis in archaeological thinking in recent years as evidenced, for example, by the papers in this symposium. In the past we were presented with lithic industries which, to judge by their descriptions, were copulating, hybridizing, evolving, adapting, and producing offspring..." (DeVore 1968: 346).

The papers by James Deetz, William Longacre, James Hill, and Robert Whallon used ceramic data from individual American archaeological sites to make inferences about social organization (demographic aspects and residence and descent rules). The papers by Howard Winters, Kent Flannery and Michael Coe, and Stuart Struever, also dealing with North American sites, were broader in scope and region oriented. More importantly, these papers adopted ecosystem and functionalist orientations for studying the archaeological record of the Formative and Classic stages. This volume also included three papers which took the new ideas to the Old World – Sally Binford's paper on variability in the Near Eastern Mousterian, James Sackett's paper on the French Upper Paleolithic, and Frank Hole's study of the early food-producing culture of Iran.

Coincidentally, in 1968 another set of eight interesting essays appeared as part of an edited volume entitled *Anthropological Archaeology in the Americas* (Meggers 1968). These essays, arising from lectures delivered during the two previous years under the auspices of the Anthropological Society of Washington, were very much in alignment with the new ideas that were already in the air; in fact three of the writers also published papers in *New Perspectives* as mentioned above. These contributions once again laid emphasis on systemic and superorganic conceptions of culture and the role of the natural environment. Stuart Struever argued for a methodological reorientation in American archaeology in order to come to grips with the new goals. James Deetz's essay dealt with issues relating to the contact period. The remaining six papers (by J. Campbell, E. Wilmsen, J. Schoenwetter and A. Dithert Jr., K.V. Flannery, W. Sanders, and D. Thompson) reflected the use of new ideas and methods in the investigation of American archaeological sites belonging to paleo-Indian and later cultural stages.

Subsequently some of the above-mentioned authors elaborated on these beginnings and completed major research projects, e.g., Flannery's (1976, 1986) work on the early food-producing cultures of the southern highlands of Mexico and Winters' (1969) work on the Riverton culture of Wabash valley in Illinois. Other major projects, which also fall within the framework of New Archaeology, include the work of MacNeish and others on the emergence of food-producing way of life in the Tehuacan valley (MacNeish et al. 1972) and Adams' work in Mesopotamia (1965, 1966; Adams and Nissen 1972).

The volume *Processual Archaeology*, edited by Johnson (2004), contains a set of another ten essays representing third-generation studies employing the approaches recommended by New Archaeology. These concern site or regional-level studies of sites belonging to hunter-gatherer and later stages and clearly show that the themes broached by New Archaeology are still vibrant in contemporary archaeology both in America and the Old World. Surely, between 1968 and the volume edited by Johnson, there have

been a good number of field studies of hunter-gatherer, food-producing, and state-level societies in different parts of the world which benefited from New Archaeology's propositions (O'Brien et al. 2005: Chaps. 3 and 4). But it may as well be the case that just as one does not always notice Darwin's name in the discussions concerning the theory of evolution, the inspiration provided by New Archaeology does not always find explicit mention.

India is one of the few regions outside the Anglo-American world which began to favorably respond to the call of New Archaeology from an early stage. Thanks to the initiative taken by Sankalia (1977) and the inspiration provided by Binford's month-long personal visit to Deccan College in Pune in 1986 to give a series of lectures on the basic premises and applications of New Archaeology, Indian archaeology began to experience the influence of New Archaeology from an early stage. The settlement system perspective has been adopted for studying Paleolithic and Mesolithic sites which were for a long time dubbed as producing only "stones" and "more stones" (e.g., Murty 1981; Paddayya 1982; Raju 1988; Mohanty 1990; Cooper 1997; Selvakumar 1997). Settlement system studies have also been undertaken with reference to the early food-producing communities of the Deccan (Dhavalikar 1988) and the Indus civilization (Possehl 2002a, b). New Archaeology's regional approach to the archaeological record was employed with excellent results for studying the medieval capital of Vijayanagara in South India. The 700 localities found in an area of 250 km^2 around this city facilitated a much better understanding of the dynamic relationships between the city and its hinterland (Sinopoli 2007). Also, the topic of formation processes has taken firm root in Indian archaeology (Paddayya 2007). It is a stunning fact that in 1963, Raymond Allchin published a comprehensive study of the Neolithic ashmounds of the Deccan, which involved not only sound traditional archaeology but also the employment of strategies like hypothesis testing, the regional approach, and the interpretation of the archaeological record in terms of human motives that later became major tenets of New Archaeology and post-processual archaeology (Allchin 1963).

Conclusion

Scientific research is dynamic and builds upon existing blocks of knowledge. Thus, it was not surprising when in 1982 Ian Hodder put forward the view that material culture items, their functional roles apart, are symbols in action and shape human minds (Hodder 1982). This was the beginning of post-processual archaeology, which emphasizes that archaeology cannot stop at the level of reconstructing past human behavior but must trace it back to human feelings, sentiments, and emotions (Flinders Petrie actually put forward this idea a hundred years ago (Petrie 1972)). Interpretation replaced explanation as the discipline's goal. As in the case of New Archaeology, this trend also soon experienced a stream of sub-trends – semiotic archaeology, archaeological poetics, hermeneutical archaeology, structuralist archaeology, phenomenological archaeology, agency theory, etc., which are fit topics for separate encyclopedic entries. Attention was also drawn to the sociological dimensions of the study of the past – gender archaeology, public archaeology, archaeology as sociopolitical action in the present, etc.

New Archaeology's propositions were for some time questioned and even derided by these more recent trends. But soon the falsity of a mind-body dichotomy, which had plagued European philosophy for centuries, began to dawn upon us, and it was then easy to appreciate that the interpretation of human cultures as ideational systems has to rest upon their study as functioning systems in the material world. The great German *litterateur*, Bertolt Brecht, expressed this notion in a few beautiful words: "Erst kommt dass Fressen und dann die Moral." It is good to note that Hodder himself has recently called for an integrated approach for decoding what he calls "human-thing entanglement" in the past (Hodder 2011).

Seen in a wider context, the traditional culture history approach, New Archaeology, and ideational perspectives, far from being mutually exclusive, are actually complementary to one

another. If one may slightly rephrase Thomas Kuhn (1977), academic tensions are not only essential but beneficial. Depending upon the nature and extent of the previous work on the archaeological record, their application will vary from area to area and from problem to problem. Much wisdom lies in the message which Buddha gave to the perplexed village folk of North India 2500 years ago: "Listen to all kinds of teachings but adopt what suits you, employing your own powers of observation and reasoning!"

Introduction

Although the Spanish conquest of Central Mexico and the Aztec capital of Tenochtitlan took a little over 2 years, the conquest of northern New Spain took 400 years to complete, using the same strategies as the original conquerors, explorers, and adventurers radiated from Mexico City in search of fame and fortune. In that search, they furthered the principal goals of the Spanish colonial enterprise: profit, evangelization, and cultural expansion, co-opting indigenous social and economic systems where possible and creating new-life ways and urban centers where convenient and viable.

Historical Background

Opening bridle paths and wagon roads was part and parcel of the expanding colonial enterprise. Many were built on preexisting trails that integrated the ebb and flow of ideas, knowledge, and commerce that was Mesoamerica. These trails were quickly converted from trails of integration to trails of destruction and subjugation. They radiated from the metropolitan capital to the newly created provincial capitals and principal ports and sustained the authority and power of the Spanish crown. Initially less than a meter wide and defined by the continual passage of *tamemes* (porters), human beasts of burden capable of carrying 35 kg on their backs, these trails had to be adapted to the needs of horses, mules, and wagons that carried far greater loads and to the needs of their drivers. They were widened, graded, and given firmer substrates. Permanent sources of drinking water and areas of forage were found. Way stations were built (Rees 1975; Lira López 2009). Initially, the old and the new modes of transportation coexisted and adapted together, but as time went by and the volume of freight increased, *arrieros* (teamsters) replaced *tamemes*.

The colonization and pacification of northern New Spain was built on the establishment of missions, mines, and market towns that formed a series of networks, or heartlands, integrated by a principal artery – *el Camino Real de Tierra Adentro* (the Royal Inland Road) – that began in Mexico City. By the late sixteenth century, that artery reached its maximum extension in northern New Mexico. Branches to the east and west covered immense areas. Toward the end of the seventeenth century, the western branch extended all the way to San Francisco, California, while the eastern branch tentatively reached the border between Texas and Louisiana (Fig. 1).

As the frontier moved further north, the distances between settlements grew, the population density shrank, and the need for protection increased as travelers were continually subject to surprise attacks and ambush by nomadic people intent on dislodging the invaders and purloining the exotic goods they carried.

While the Spanish terms *fuerte* and *presidio* can be translated into the single English word "fort," in New Spain, they were distinct classificatory terms. Forts, such as the Fuerte de San Juan Ulúa (Veracruz) or the Fuerte de San Diego (Acapulco), were major military defensive installations designed to defend sea ports from foreign invaders. As such, they tended to be strategically located and heavily armed. They were generally built and rebuilt by military engineers.

Presidios, derived from the Latin *præsidium* meaning frontier defensive outpost, were

New Spain: Forts and Transport Archaeology, Fig. 1 Road network in New Spain in the early 1800s. (Map created by P. Fournier)

generally landlocked, considerably smaller, and less robust than forts. When initially built in New Spain, they were expected to protect and defend the civilian settlements on the northern frontier of New Spain and the commerce that flowed along the *Camino de la Plata* (Silver Road), precursor to the *Camino Real de Tierra Adentro*. At that time, they may have been manned by no more than a dozen soldiers and officers garrisoned in a small blockhouse. By the beginning of the eighteenth century, the nature of the threat had changed, and the presidios had evolved into much larger rhomboid or quadrilateral structures that included one or more towers, which when fully complimented may have housed as many as a hundred soldiers and officers (Fig. 2).

The new garrisons formed a defensive line from California to Texas designed to keep out native populations to the north and those to south of the Spanish controlled areas. In the case of *presidios* located in the arid lands of northern New Spain, the soldiers and their families lived in and nearby the architectural complex and often engaged in small-scale agriculture and cattle raising outside it to complement their official rations. The troops were of mixed ancestry, the product of several generations of Spanish, indigenous, and African liaisons; some *presidio* soldiers had relations with and sometimes married native women.

Key Issues

Forts

Forts were massive defensive structures designed within the parameters of European siege warfare to defend crucial trade nodes in New Spain such as the ports of Veracruz, the principal point of access linking the colony to the Iberian Peninsula, and Campeche in the southern fringes of the Viceroyalty, a major source of tropical woods and dye stuffs. The structures visible today were built in the late eighteenth century to replace earlier earthworks that had failed to deter attacks by pirates, buccaneers, and corsairs.

The lack of concerted archaeological research is evident. Excavations have been either subsidiary to the installation of modern infrastructure or auxiliary to the conservation, restoration, and reconstruction of public places or specific buildings.

New Spain: Forts and Transport Archaeology, Fig. 2 The *presidio* line of northern New Spain in 1772. (Map created by P. Fournier and A. Avila)

N

In New Spain, the wealthiest people lived in urban centers located in the highlands, far from unhealthy port towns. In the case of the port of Veracruz and the San Juan de Ulúa fort, the archaeological record indicates that the construction of inns (*ventas*) on the mainland in front of the fort preceded the construction of the earliest massive defenses. The material evidence also shows that the nascent Veracruz was little more than a shanty town until the middle of the eighteenth century (Hernández Aranda 2006). However, after the harbor and the town were devastated by fires and hurricanes several times, in 1737, orders were issued to construct walls surrounding the settlement and to replace the all-pervasive wooden huts with masonary buildings. The residents of Veracruz did not live in opulence. They were middle- to low-class merchants from Spain and New Spain; store and inn owners; sailors, porters, and soldiers stationed at the fort; and servants, African slaves, and free mulattos. Excavations at residences, inns, a shipyard site, and in the San Juan de Ulúa complex have uncovered architectural fills, leaving activity areas ill defined. The associated ceramics found were largely tablewares: 70% plates and 15–12% cups and mugs, but unlike assemblages recovered from mixed deposits in urban centers (Hernández Aranda 2004) such as Mexico City, there were no clear indications of class distinctions.

Although not strictly a fort but a walled city supported by bulwarks and redoubts, Campeche, a town built on an existing pre-Hispanic settlement, has provided a wide range of ceramics including sixteenth century majolica from Spain, seventeenth and eighteenth century majolica from Puebla, and the ever-present glazed or unglazed coarse earthenwares and olive jars. Nineteenth century artifacts underline the role of international trade in Campeches' growth and development (e.g., Ojeda Mas 1998).

Presidios

In the case of *presidios*, their setting and construction ranged from simple adobe houses to walled quadrangles protected by one or more towers and housing barracks, a chapel, officers' quarters, a smithy, and a gunpowder house. There would have been only one entrance. Often, there was a corral against one of the external walls. Many of the buildings may have been incorporated into, or abutted, the enclosing wall. The exterior walls were almost 2 m high and may have included firing slits and some form of interior bench or walkway that would have given the defenders a height advantage over any potential attacker whether mounted or on foot. They were not provided with canons and generally lacked an interior water source that would have succored them in times of a siege. Luckily, they rarely had to face such an eventuality. Their marauding challengers never, or rarely, saw the need to attack these static bulwarks. They found it easier to avoid them and go after their weak spot: the horse pasture. Due to the arid nature of the local environment and the limited ability to grow fodder on whatever bottom lands that might have been available, the presidios' horses all too often had to be grazed away from the presidio itself where they were exposed to ambush and stampede. It was also easier and more profitable to attack the pasture, leaving the presidial cavalry on foot and at a significant disadvantage until the horses could be replaced (Fig. 3).

Rex Gerald's (1968) seminal study examined and summarized what was known about the architecture and artifacts of the line of *presidios* that extended from California to Chihuahua. Williams (1991), Costello and Walker (1987), and Voss (2008) have studied and summarized different aspects of the history, architecture, and associated features of military settlements in Sonora, Arizona, and California. Subsequent research has focused on a number of *presidios* across the Spanish Borderlands (e.g., Bense 2004) such as El Carrizal, Chihuahua (Brown et al. 2004), and Aguaverde, Coahuila (Turpin and Eling 2004). Nonintrusive research techniques have included subsurface interface radar, proton magnetometry, and EDM topographic surveys (e.g., Brown et al. 2004). Stratigraphic excavations of architectural features have recorded both construction techniques and materials and helped to identify and interpret activity areas (e.g., Bense 2004; Brown et al. 2004). In a few instances, human burials have been recovered and subject to relevant osteological studies including osteometric analyses of morphological features of crania and teeth (Costello and Walker 1987). Zooarchaeological and macro-botanical remains have also been studied to better understand living conditions and foodways (e.g., Pavao-Zuckerman and LaMotta 2007).

Handwrought and cast-iron items, various metal utensils, glass containers, lead musket balls, gunflints, clothing and personal items, and other material remains have been analyzed (e.g., DiPaolo Loren 2001; Fox et al. 2009). Indigenous, Hispanic, Chinese, and European ceramic wares have been used as chronological markers and have helped to identify the extent and nature of regional exchange systems. Neutron activation analyses were applied to understand the colonial economic adaptation of plain ceramics, lead-glazed wares, and majolica from the Presidio San Francisco district. The results illustrate the development of local pottery production of plain and glazed wares, exchanges between mission sites, and the relevance of imports from Mexico in the daily lives of people of European descent in the fringes of New Spain (Skowronek et al. 2009).

The most common wares were regionally made brown wares produced by both *mestizo* (people of indigenous and European descent) and indigenous groups (e.g., Brown et al. 2004). While some results suggest there were few social markers in the archaeological record, others suggest that colonists sought to differentiate themselves from the indigenous population through their material possessions (e.g., Brown et al. 2004; Voss 2008). In this case, ethnogenesis provides a theoretical framework to help understand the creation and continual evolution of cultural identities, with special reference to gender and sexuality (Voss 2008).

While the specific ceramic assemblage from each site is distinct, the ceramic assemblage from El Carrizal, Chihuahua would seem to be

New Spain: Forts and Transport Archaeology, Fig. 3 Topographic map of Presidio El Carrizal, Chihuahua (Brown et al. 2004: 278)

fairly representative. This consisted of 1,509 sherds of which 80.78% were regionally produced brown wares, plain (95.32%), decorated red-on-brown (4.35%), and burnished tradewares (0.33%). The plainware vessel forms included jars, bowls, platters, basins, *comales* (corn tortilla griddles), and discs made from recycled sherds. The bichrome wares included jugs, basins, bowls, and jars (Brown et al. 2004). The remaining 19.22% of the ceramic materials was composed of majolica tradewares from Puebla, Guanajuato, and probably Aguascalientes (8.48%); lead-glazed ceramics from western and central Mexico (4.31%) or from northern New Spain (Presidios Green, 4.17%); British creamware (0.13%); British and Dutch white wares (0.99%); Mexican white wares (0.07%); Chinese porcelain pertaining to the Qing dynasty (0.33%); olive jars (0.20%); Tonalá burnished ceramics (0.20%), from western Mexico; coarse earthenwares (0.13%); and industrial porcelain (0.20%) (Fig. 4).

New Spain: Forts and Transport Archaeology, Fig. 4 Indigenous *red-on-brown bowl* fragments from *presidio* El Carrizal

These data indicate that Spanish-tradition ceramics used to display status in urban colonial culture were scarce because of distance, cost, and difficulties in transport. Ceramic forms, dominated by native brown wares, were employed for

a variety of culinary, storage, table-service, lighting, and amusement purposes, evidencing the distinct residential character of the military settlement.

Transport and Way Stations (*Parajes*)

Two groups of sites, the first in the Valle de Maltrata, Veracruz, and the second at Paraje de San Diego, in southern New Mexico, can be used to demonstrate the changes from foot path to bridle path to roadway and on to the introduction of the railroads and expressways.

Valle de Maltrata, Veracruz

The Valle de Maltrata is a narrow crucial pass from the coastal plain of Veracruz to the Mexican Highlands and as such has seen innumerable travelers over the last 5,000 years or more. First, in pre-Columbian Mesoamerica, *tamemes* carried on their backs trade goods and tribute through the mountains. During the colonial period, the introduction of horses, mules, and wagons saw an increase in the commercial traffic and the introduction of cobblestone avenues. Then, in the late 1800s, the railroad replaced the avenue, and in time, the expressway replaced the railroad.

As a result of archaeological surveys, stone-paved sections of several roads in the Valle de Maltrata have been registered. Although details are not provided (Lira López 2009: 140), their width and the use of switchbacks and massive, arched, stone bridges indicate that wagon and mule trains crossed the mountain passes easily. Surface collections recovered in and around the zone where causeways are located date from the early colonial to the modern period. The Early Colonial and Later Colonial period are defined by distinctive majolica types, while the Modern period is defined by a dramatic increase in metallic artifacts and nineteenth century majolica types (Lira López 2009).

Paraje de San Diego, New Mexico

The Paraje de San Diego is a well-known cluster of sites that includes a camp ground or way station that was used by Juan de Oñate, conqueror of New Mexico, in 1598. Depending on the direction of travel, it provides water before or after crossing the Jornada del Muerto, a 90-km stretch of the Camino Real de Tierra Adentro that lacks adequate water. The ceramic and artifact assemblages (e.g., majolica, lead-glazed pottery, olive jars, Chinese porcelains, indigenous ceramics, glass, and metal) indicate that the site was commonly used from the early eighteenth to the mid-twentieth century; moreover, low percentages of pre-Columbian pottery were found (e.g., Fournier 1999). The research began with a metal detector survey to determine site boundaries which was followed by an intensive surface collection that provided material that also could be conveniently divided into three periods. The subsequent excavation provided a ceramic assemblage of 668 sherds of which the majority of pieces are limited to the period, c. 1650–1680. Forms concomitant with the preparation and serving of food are the most common: soup plates (30%), bowls (12%), cups (20%), and jugs or pitchers *(jarros)* (3%). Cooking vessels include jars (*ollas*) (24%) and basins (*cazuelas)* (1%); water jars are limited to 5% (Staski 1998; Fournier 1999). The limited morpho-functional variability is a result of the nature of activities carried out at the site, used as a camp for repeated short-term occupation, where food was cooked and served and water was gathered (Staski 1998) by travelers and merchants who transported goods along the Camino Real.

Ongoing investigations include studies of *haciendas* and mining towns along the Camino Real (e.g., Fournier and Blackman 2010) as well as an interdisciplinary and inter-institutional research project – "Cultural Heritage and Identity," codirected by J. Pacheco, P. Fournier, and M.A. Morales – extending from central Mexico to Durango (http://promep.sep.gob.mx/ResultadosConvocatoriasPTC/2012/Redes.htm).

Future Directions

As they develop, the material correlates of the archaeology of forts and transportation in New Spain will provide a better understanding of the daily lives of those that rarely make it into the history books such as the soldiers, stevedores and teamsters, and their families. Each *presidio* was

built in the colonial period and reflects both specific local needs and the overarching goals of the viceregal authorities. They share a common cultural sequence defined by the ebb and flow of the viceregal policies and modified by regional political, socioeconomic, and military considerations. However, only a limited number of *presidios* have been partially excavated, and as a result, a concerted effort is warranted to expand the study of forts and transportation before the relevant sites are destroyed by neglect, vandalism, and rural and urban development (Figs. 5 and 6).

Steps have already been taken to address this. In 1994, a cultural, academic, and technical cooperation agreement was signed by the National Institute of Anthropology and History (INAH), the

N

University of New Mexico, and the Office of Cultural Affairs of New Mexico to develop projects related to the research and conservation of the natural, cultural, archaeological, historical, and paleontological heritage of the Camino Real de Tierra Adentro (http://www.oas.org/udse/cic/ingles/web_cic/programamexicoheritage.htm). However, while the idea was to promote Royal Road research, tourism, and dissemination, the impact and results have been limited (e.g., Pacheco and Sánchez 2000).

The Camino Real traverses ten states in Mexico, without counting its eastern and western branches. Most scholars often carry out their work in isolation from their colleagues and seldom join efforts to integrate research results for the understanding of the social, economic, and political past processes associated with this road. In Mexico, archaeological research is governed by federal laws and INAH's guidelines, always privileging the pre-Columbian heritage. Scarce funding is a major problem for the development of interdisciplinary projects with a historical archaeology component that investigate, document, protect, and promote public understanding and appreciation of the Camino Real.

In anticipation of the designation in 2000 of El Camino Real de Tierra Adentro National Historic Trail in Texas and New Mexico spanning more than 650 km of the Royal Road, a number of archaeological studies – both surveys and excavations – were undertaken. Many of the results have been published in the Bureau of Land Management Cultural Resources Series (e.g., Palmer 1993; Palmer and Fosberg 1999). Since 2003, El Camino Real de Tierra Adentro Trail Association (CARTA n.d.), in collaboration with the National Parks Service, the Bureau of Land Management, the New Mexico Department of Cultural Affairs, and various Mexican organizations such as INAH, state cultural institutes, and local universities, has striven to highlight the importance of the Camino Real de Tierra Adentro and to promote its protection and study, as well as to facilitate the participation, involvement, and understanding of the communities along the trail as they celebrate the many facets of their multicultural and multiethnic history, the traditions of a living trail (http://www.caminorealcarta.org/aboutCARTA.htm).

Most recently, in 2010, 60 historic sites along the Mexican section of the Camino Real de Tierra Adentro were added to UNESCO's World Heritage List. However, most of them have not experienced an increase in tourism or substantial economic development. As mentioned, many historical landmarks continue to be subject to neglect and vandalism. In a country where the tourism industry is a major economic force, initiatives for engaging government institutions in the protection and in-depth study of the sites along centuries-old trajectory of the road, and public involvement through educational and outreach programs to promote the cultural importance to the communities that it served are pending tasks.

Niah Cave (The West Mouth)

Huw Barton
School of Archaeology and Ancient History, University of Leicester, Leicester, UK

Introduction

Niah Cave is one of a large system of caverns situated at the base of a large limestone massif in the lowland rainforests of Sarawak, Malaysia, and is one of the largest Palaeolithic sites in Southeast Asia. The main archaeological site is the West Mouth, an enormous cavern that links via internal passages to several smaller cave mouths, one of which, Lobang Hangus, also contains Palaeolithic deposits. The West Mouth contains evidence of human activity dating from at least 50,000 years ago until the historic era. The site also contains a long history of human

Niah Cave (The West Mouth), Fig. 1 View looking east into the main E-Series trench excavation areas in the West Mouth. Tom Harrisson and others pictured working on a north-facing section. (Image courtesy of Dr. Ipoi Data, Sarawak Museum Image Archive)

burial dating from 12,000 BCE until 200 BCE that encompasses a rich tradition of depositional practices including flexed burial, secondary jar burial, cremations, and supine coffin burials (Lloyd-Smith 2009).

The site was first excavated by a team led by the curator of the Sarawak Museum, Tom Harrisson and his wife Barbara from 1954 to 1967 (Fig. 1), by Zuraina Majid in 1977 (Zuraina Majid 1982), and most recently by Professor Graeme Barker, who directed the Niah Cave Project from 2000 to 2003. The aim of the original excavation was the discovery of early human remains following the remarkable discoveries of *Homo erectus* (*Pithecanthropus erectus*) by Eugene Dubois at Trinil, Java, Indonesia, in 1891. The site and Tom Harrisson became world famous with the discovery of anatomically modern human remains, a skull and tibia, in 1958, that were radiocarbon dated to c. 40,000 years BP (Harrisson 1959). While the original excavation team left extensive records of their work with the Sarawak Museum, a final report on the site was never published.

Key Issues/Current Debates/Future Directions/Examples

Harrisson was innovative at the time for the extensive use of the new radiocarbon dating technique and use of other specialists such as the geologist, Dr. Schroder, from the Brunei Shell Petroleum Company, to recover pollen from the cave sediments to understand the Pleistocene environment, and Lord Medway, now Earl of Cranbrook, to analyze and interpret the cave fauna. His wife Barbara, while not a trained archaeologist, ran the excavation during Tom's absences, was present during the initial discovery of the Deep Skull, and professionally directed the recovery of human remains from the extensive and complex late Holocene cemetery also discovered in the West Mouth. A final report on the cemetery excavations was published by Barbara Harrisson in the Sarawak Museum Journal in 1967 (Harrisson 1967).

A major flaw of Tom Harrisson's site interpretation was that he believed sediments had accumulated gradually at a relatively fixed rate of 1 in. (2.5 cm) every 521 years (Harrisson 1958). Harrisson directed excavators to remove sediment in arbitrary horizontal spits, unwittingly cutting through a complex and often, convoluted set of sedimentary sequences. As a result there remained serious doubts among the archaeological community about the veracity of Harrisson's chronological and typological interpretations, leaving Niah sidelined from major archaeological debates in the region (Spriggs 1989; Bellwood 1997).

The Niah Caves Project

The Niah Caves Project (NCP), 2000–2003, was instigated to resolve several unanswered questions about the precise chronology of the site, the age of the Deep Skull, and details of the stratigraphic and cultural sequences (Barker et al. 2000, 2001, 2002a, b, 2003, 2007, 2011). The project was multidisciplinary involving experts in a wide range of fields to address the complex formation history of the site and draw as much information about occupation history from the remaining sediments, while minimizing

further physical impact to the site. The NCP investigations recovered a remarkable record of organic remains from the Pleistocene layers of this site, including animal bone, fish bone, mollusks, macroplant remains, starch granules, and organic tools including attached bindings. From these investigations excavators have been able to reconstruct details of diet and hunting technology.

Reanalysis of the Deep Skull determined its age to range between 42,000 and 39,000 years old, based on ABOX radiocarbon dates of nearby charcoal and uranium-series dating of bone fragments from the cranium (Barker et al. 2007). The skull and tibia fragments remain the oldest modern human remains in Southeast Asia. Further radiocarbon dating of charcoal associated with stone tools, burnt bone, and hearths indicates human occupation at Niah from at least 50,000 years ago (Barker et al. 2007; Higham et al. 2008). The recovery of flaked stone below these radiocarbon dates suggests possible earlier occupation, but attempts to date these and lower layers using optically stimulated luminescence were unsuccessful (Stephens 2004).

Organic remains from the site provide a rare insight into the technical capabilities and knowledge of these late Pleistocene foragers. Faunal remains include large numbers of bearded pig, *Sus barbatus*, Malay tapir, *Tapirus indicus*, bovids and sambar deer, *Cervus unicolor*, as well as a range of reptiles, fish, and bats. They harvested freshwater snails such as the gastropod *Paludomus everetti* and the mussel *Ctenodesma borneensis*. Plant foods represented include a wide range of fruits, nuts, and tubers, and these indicated that people were able to detoxify poisonous plants from the Late Pleistocene. After the Last Glacial Maximum, there is evidence that people may have engaged in burning forest edges to enhance plant and animal productivity (Hunt and Rushworth 2005).

Charred nut fragments included fragments of the toxic plant, *Pangium edule*, recovered in deposits dating from at least 40,000 years ago (Barton and Paz 2007). This plant is deadly to humans if not properly processed; even so fermented nuts remain a popular food today in some parts of Malaysia. From deposits dating to around 20,000 years ago, macro-remains of several yams and tuberous plants were recovered, including the toxic yam, *Dioscorea hispida*, and the aroid known as taro, cf. *Colocasia* elim. *Esculenta*, as well as other unidentified tuberous remains (Barton and Paz 2007). Recovery of starch granules from the cave sediments revealed further use of yams including cf. *Dioscorea* sp., as well as the forest aroid *Alocasia longiloba* (Barton 2005). The latter plant is avoided as a food today, as it is considered too itchy, but produces large rhizomes, which could have been eaten in the past. Starch granules of the sago palm *Eugeissona utilis* were also recovered from deposits dating to 40,000 years ago, indicating the use of this palm as a food source at this early time (Barton 2005). These findings show that early foragers had knowledge of useful sources of starchy foods such as yams, rhizomes, and starch storing palms, and they also knew how to detoxify some very poisonous plants.

Bone points were recovered from early Pleistocene contexts, but none have been securely dated. The earliest bone point comes from Trench HR/1 at 120–123 in. (300–307.5 cm) (corresponding to c. 40,000 years ago). Analysis of wear patterns on this point and eight others suggests their use as multifunctional tools, including for crafts like basketry (Rabett et al. 2006). A total of fourteen bone points from Lobang Hangus (a cave entrance on the opposite side of the limestone massif to the West Mouth), dated from 14,000 years ago, were identified as projectile armatures, probably part of a bow and arrow technology (Piper and Rabett 2009: 562). From the West Mouth, bone bipoints, including examples made from the spines of freshwater stingrays, were dated to 12,000 years ago (Barton et al. 2009). Several of these retained traces of hafting resins and fiber bindings. It is thought that these were part of a composite spear technology, such as a multipronged fishing leister.

The lithic technology is relatively informal throughout, consisting primarily of unretouched quartzite flakes struck from river pebbles and cobbles with some use of quartz, chert, shale, and limestone. Organic residue analysis of the lithic technology revealed use of silica-rich plants like

bamboo, rattans, and palms from the earliest levels. Several tools from layers dating to around 40,000 years ago had been used to work plant resins, suggesting use as mastics and composite organic tools might date from the earliest periods of human occupation at this site. There is a relatively sudden addition of ground stone, cobble mortars after 17,000 BP associated with an increase in woody ash deposits that might suggest a change in site use intensity at this time. Later Holocene layers contain polished pebble axes and a variety of adzes, but there are no secure dates for the establishment of these traditions in the West Mouth.

Niah Caves: Role in Human Evolution

Graeme Barker
McDonald Institute for Archaeological Research, University of Cambridge, Cambridge, UK

Introduction

The Niah Caves of coastal Sarawak in northern Borneo (N 3° 48′ 54.6, E 113° 46′ 52.3″) have been a subject of archaeological interest ever since the mid-nineteenth century, when the naturalist Alfred Russel Wallace visited Sarawak in 1855 to collect biological specimens and, though he was unable to visit the caves, reported their likely significance for anthropological research to Charles Darwin and Thomas Huxley (Sherratt 2002). The 1950s and 1960s excavations of Tom and Barbara Harrisson brought the caves to international attention, especially those in the West Mouth of the Great Cave (Fig. 1), in particular their discovery of an anatomically modern skull that they dated to c. 40,000 BP, the so-called Deep Skull (Fig. 2). Renewed investigations since 2000 have confirmed the central importance of the site for human evolution studies in Southeast Asia (Barker et al. 2007, 2013; Barker 2013).

Definition

The Niah Caves lies within the Gunong Subis, a steep-sided limestone massif close to the northern shoreline of Sarawak. In the 1950s and 1960s, Tom and Barbara Harrisson conducted excavations in many of the cave entrances, but the largest, and most important for early prehistory, were those in the West Mouth of the Great Cave. In February 1958, a team led by Barbara Harrisson discovered in the deepest part of their excavation near the front of the West Mouth (the "Hell Trench") the skull and other bones of an anatomically modern human (Brothwell 1960), its antiquity indicated by charcoal found the previous year near the skull findspot which was dated by the then revolutionary method of ^{14}C dating to 39,820 ± 1012 BP (GrN-1339C; calibrated, the date would be 42,391–45,629 BP) (Harrisson 1958). Other finds indicated that the West Mouth was used for human occupation and burial from the time of the "Deep Skull" more or less to the present day, and their excavations in the other entrances of the Great Cave and other caves elsewhere in the Gunong Subis yielded further evidence for human settlement and/or burial at different periods of the past. The work gave the caves iconic status in the archaeology of Island Southeast Asia as having the longest sequence of human occupation known in the region (though older fossils have since been found elsewhere in the region, e.g., Mijares et al. 2010; Demeter et al. 2012).

For a number of reasons, the Harrissons were never able to publish their excavations in final form, and despite the many interim papers they published, some of their discoveries, stratigraphic findings, and interpretations were controversial. One of the criticisms raised by scholars subsequently was that, given the fact that caves frequently have complex dipping deposits, the excavation method of horizontal spits used by

Niah Caves: Role in Human Evolution, Fig. 1 The West Mouth of the Great Cave; the archaeological reserve is on the far *right*, immediately in front of the tourist boardwalk visible on the skyline. (Photograph: Graeme Barker)

the Harrissons (Fig. 3) was likely to have mixed together material of different ages. Also, a key component of their dating was extrapolation by depth, Tom Harrisson arguing that the most common deposit in the West Mouth, what he called the "pink and white layer," accumulated as a drizzle of sediment from the cave roof at a steady and constant rate, but a simple depth-age relationship in cave sediments ran counter to the experience of most cave excavators. The major question was whether the Deep Skull was really as old as Tom Harrisson claimed. The Malaysian archaeologist Zuraina Majid conducted further smaller-scale excavations in the West Mouth that made a notable contribution to understanding the Niah sequence (Zuraina Majid 1982), but significant uncertainties remained. This was the context for a further program of fieldwork and related laboratory, artifactual, and archival studies (the Niah Caves Project, hereafter the NCP) that began in 2000, coordinated by Graeme Barker (University of Cambridge). The main fieldwork took place between 2000 and 2004, and analytical work has continued ever since, focussed both on materials from the new fieldwork and the rich assemblage of archaeological finds – which include animal bones, human bones, shells, stone tools, bone tools, pottery, textiles, and beads – from the previous excavations.

Key Issues/Current Debates/Future Directions/Examples

The NCP investigations in the West Mouth have defined a series of major geomorphic and palynological phases bracketed by new ^{14}C dates (Gilbertson et al. 2005; Higham et al. 2008; Fig. 4). In the period >50,000–37,000 BP, colluvium (defined as Lithofacies 2C) slid down from the cave lip into a natural basin on its interior side, where it interbedded with silts and clays formed by episodes of streamflow from the cave interior (Lithofacies 2). The climate alternated between warmer and wetter, and cooler and drier, conditions, with corresponding landscape changes between lowland forest, mangroves, and coastal swamps (in the former) and dry montane and lowland forest (in the latter). It became progressively drier and cooler after c. 45.000 BP, though there were still episodes of hot wet climate when lowland rainforest and mangroves developed in the vicinity of the caves. Around c. 35,000 BP, possibly triggered by a major roof fall, earthquake, or very wet episode, there was a major collapse of wet guano (Lithofacies 3) in the West Mouth interior that caused a mudflow that filled the West Mouth basin, deforming and covering the existing sediments. Thick sequences of archaeology-rich brown silts (Lithofacies 4) then

Niah Caves: Role in Human Evolution, Fig. 2 (*top*) The discovery of the "Deep Skull." The label to the *left* of the partially excavated skull refers to the location of the charcoal found the previous year and dated to c. 40,000 BP; (*bottom*) the Deep Skull after restoration (*top*) and a modern human skull (*bottom*). (Photographs reproduced with permission of Sarawak Museum)

built up across the front of the West Mouth, forming from soon after the mudflow to the Early Holocene c. 8500 BP. Most of the latter sediments were removed by the earlier excavators but enough remain to indicate that human activities in the Terminal Pleistocene and Early Holocene included the digging of pits and their filling with food refuse. The windblown component in Lithofacies 4 and the associated palynological record suggest an overall trend towards a drier and more open landscape in this part of northern Borneo c. 20,000–10,000 BP, before the hot and wet climate of coastal Sarawak today, and dense rainforest, developed with the onset of the Holocene.

Fragments of the Deep Skull (which belongs to a teenage girl) have been dated using the uranium-series method to about 37,000 years ago (Barker et al. 2007). The NCP has established its likely stratigraphic position within the Lithofacies 2 sediments but has obtained ^{14}C dates on charcoal from *higher up* the profile of c. 40,000 BP. Furthermore, the sediments cemented within the skull are very different from those of Lithofacies 2 in terms of their bulk characteristics, geochemistry, and palynology, and most strikingly include large granite crystals, the nearest sources of which are a considerable distance away in the Rajang Valley and on Mount Kinabalu. The discrepancies in the dating, sedimentology, geochemistry, and palynology are consistent with the skull and its associated long bones (a left femur and right proximal tibia: Krigbaum and Datan 2005) having been in a pit dug down from the Lithofacies 4 sediments into the Lithofacies 2 sediments, i.e., that they are the result of deliberate burial rather than, say, parts of a body dumped on the cave lip that slipped down naturally into the natural basin behind it and was incorporated in the Lithofacies 2 stream sediments there (Hunt and Barker 2013). An intriguing further hint at ritual activity associated with the heads of the dead is traces of a red wash, probably from a tree resin (Pyatt et al. 2010), on the interior surface of human skull fragments that have been found among the vertebrate fauna from the Harrisson excavations, from the same depths as the Deep Skull.

Evidence for hominin presence in the West Mouth goes back to c. 50,000 BP. Dates of this antiquity on charcoal have been obtained from excavating one of the surviving Harrisson balks (HP/6) in the Hell Trench (Fig. 5), from a series of organic-rich "palaeosurfaces" full of charcoal and ash, with occasional humanly struck stone

Niah Caves: Role in Human Evolution, Fig. 3 Tom Harrisson excavating in 1958 in the West Mouth of Niah Great Cave. (Photograph reproduced with permission of Sarawak Museum)

flakes and numerous fragments of butchered animal bone. These palaeosurfaces, formed of organic debris slipping down from the cave lip into the basin within the Lithofacies 2C colluvium, appear to equate to the rich "bone-under-ash layer" that the Harrissons discovered in their basal spits; charcoal samples from the latter, curated in Sarawak Museum, have yielded dates of comparable antiquity to those from the excavated balk. Hominins were regularly visiting the West Mouth from c. 50,000 BP to the period when the Deep Skull was deposited, their visits resulting in the accumulation of lenses of ash, charcoal, and other cultural refuse along the front of the West Mouth entrance. There is no human skeletal material to demonstrate conclusively that these remains were deposited by groups of *Homo sapiens*, as opposed to other forms of hominin present in Island Southeast Asia at this time, notably *Homo floresiensis*, but the identical nature of the depositional activities and material culture in the earliest layers compared with those associated with the Deep Skull makes a very strong case that they were. A 1.5-m deep sounding excavated after the removal of the HP/6 balk, below where it stood, found fragments of butchered bone and a humanly struck jasper flake in the basal context reached, indicating some kind of definite hominin presence before 50,000 BP. This is beyond the range of radiocarbon, and unfortunately, the West Mouth sediments lacked the quartz grains essential for OSL dating, but the finds clearly imply that 50,000 BP can be treated as a *terminus ante quem* date for hominins, almost certainly *Homo sapiens*, in the Niah Caves.

The palynology of the cave sediments, the vertebrate fauna and molluscs from the Harrisson and NCP excavations, and macroscopic plant remains – phytoliths and starch grains – indicate that these hominins foraged

Niah Caves: Role in Human Evolution, Fig. 4 Schematic representation of the Late Quaternary lithostratigraphy of the northern part of the West Mouth of the Great Cave (Revised from Gilbertson et al. 2005). The present surface of the surficial deposits is the result of earlier excavations. Heights are given with reference to the site datum (~50 m above sea level). (Illustrations: Tim Absalom)

around the Niah Caves in a mosaic landscape that included montane forest (on the Gunong Subis massif), open woodland, scrub, lowland dipterocarp rainforest, riparian swamp forest, and mangrove swamp, interspersed with lakes or large rivers, smaller fast-flowing streams, and stagnant ponds (Barker et al. 2007). They especially hunted the bearded pig along with a wide variety of other prey including arboreal species such as orang-utan. There are hints in the age composition of the fauna that trapping or snaring may have been employed as well as spearing. They collected a wide range of molluscs from rivers, streams, ponds, and swamps,

Niah Caves: Role in Human Evolution, Fig. 5 Excavating the Harrisson balk HP/6 in the Hell Trench (looking south). The excavator is trowelling one of the ash- and organic-rich layers dated to c. 45,000 BP that form part of the overall body of colluvial sediments (Lithofacies 2C) that dip east into the cave from the entrance lip. A similar organic-rich layer is visible as the white smears in the balk behind him. (Photograph: Graeme Barker)

and fished these same localities. Some of the most remarkable evidence for the foraging systems of the Niah modern humans is a suite of macroscopic and microscopic botanical remains recovered from the new excavations: nuts, fruits, tissues (parenchyma) of tuberous plants such as yam and swamp taro, and starch grains of sago palm – plants that needed time and effort in the case of sago (to extract the pith) and in many cases careful processing to remove toxins. Peaks in *Justicia* pollen suggest that people were also burning forest edges to improve the productivity of forest clearings for plants such as tubers (Hunt et al. 2007), a strategy that would have improved their own plant food supply and also attracted animals such as pigs to these locations. Biomass burning of this kind is also known from New Guinea at this time (Summerhayes et al. 2010).

The Niah Caves may not tell us when anatomically modern humans first reached Sundaland, but they provide rich evidence for the latter's presence here from c. 50,000 BP, how they managed their subsistence activities, the climatic and environmental conditions in which they lived, and hints at their ritual lives. To collect the range of fauna and flora represented in the archaeological record of the West Mouth in this period required ingenuity, a considerable degree of targeting, and forward planning. Niah is currently the only site in Southeast Asia and Australia in the 50,000–35,000 BP time bracket with a well-dated human fossil associated with detailed evidence for the behavior of that hominin, and in this case, they are both strikingly "modern."

Nicholas, George P.

Julie Hollowell
Department of Anthropology, Indiana University, Bloomington, IN, USA

Basic Biographical Information

George P. Nicholas (b. 1953) knew he wanted to become an archaeologist by the age of eight. His first archaeological fieldwork was during summers as a high school student enrolled in the Franklin Pierce College (New Hampshire) archaeological field school, directed by Howard Sargent. Nicholas received his B.A. in Anthropology from Franklin Pierce in 1975 and his M.A. from the University of Missouri–Columbia in 1978, supervised by William Marquardt and W. Raymond Wood. In 1976–1977, he was the archaeologist for the New Hampshire Water Commission, followed by a short stint as a Research Associate at Phillips Exeter Academy in New Hampshire. In 1978–1980, he did postgraduate research at the University of Maine's Institute for Quaternary Research. From 1983 to 1990, he pursued his doctorate at University of Massachusetts–Amherst under the supervision of Dena Dincauze and was a Research Associate with the American Indian Archaeological Institute, working with Russell Handsman. His Ph.D. was awarded in 1990 for a dissertation on early postglacial land-use patterns and wetland ecology at Robbins Swamp (CT). In 1990, Nicholas with his wife, Catherine Carlson (also an archaeologist), and their two sons moved to British Columbia. Beginning in 1991, Nicholas developed and directed a university-based program in Indigenous Archaeology for Simon Fraser University (SFU) and the Secwepemc Cultural Education Program located on the Kamloops Indian Reserve (Fig. 1). At the time, this was the only postsecondary archaeology program for Aboriginal students in Canada. From 1991 to 2004, Nicholas directed 12 archaeology field schools and numerous research and cultural resource management projects, providing training to

Nicholas, George P., Fig. 1 1991 Secwepemc/Simon Fraser University Indigenous Archaeology Field School, Kamloops, British Columbia: (*left* to *right*) Mel Seymour, Steve Lawhead, Petrina Schooner, George Nicholas, Diane Biin, Dean Billy, Gladys Baptiste, Debbie Jules, Laurie Kennedy, John Jules, Percy Casper, and Donna Dillman. (Photo courtesy of George Nicholas)

several hundred Aboriginal students in a setting where students were always considered part of the research team. Many of his students now work for various First Nations governments or have found full- or part-time employment in cultural resource management, criminal forensic investigations, museums, and other archaeology-related fields. During this time, he was also Project Archaeologist for a 6-year study of Secwepemc People and Plants (directed by Nancy Turner) and a collaborator on the Project for the Protection and Repatriation of First Nation Cultural Heritage (directed by Catherine Bell and Robert Paterson). In 2006, upon becoming a full professor, Nicholas moved to the main SFU campus in Burnaby, BC, where he teaches, among other things, archaeological theory, Australian archaeology and ethnography, and lithic technology (Fig. 2).

Nicholas served as editor in chief of the *Canadian Journal of Archaeology* from 2001 to 2007 and currently is coeditor (with Julie Hollowell) of the World Archaeological Congress *Research Handbooks in Archaeology* series, published by Left Coast Press. He is an adjunct faculty member in archaeology at UMass–Amherst and at Flinders University in Adelaide, South Australia.

Major Accomplishments

Over his career, Nicholas has directed numerous fieldwork and research projects in western Canada and the northeastern United States from academic-based research to community-oriented archaeology training and cultural resource management projects. In the 1970s and 1980s, his primary research interests encompassed environmental archaeology and human influences on landscape in the Northeast, with a focus on the role of wetlands on landscapes occupied by hunter-gatherers. His article in *Current Anthropology* (1998) examined this topic

Nicholas, George P., Fig. 2 George Nicholas in Kamloops, BC 1995. (Photo by Shauna Huculak)

from a global perspective, noting how widespread and long-lived the association between humans and wetlands has been and documenting how attention to wetlands reveals significant and often unexpected evidence of distinctive human activities, not found elsewhere. Nicholas also edited *Holocene Human Ecology in Northeastern North America* (Plenum, 1998), which challenged conventional thinking about the way humans influenced and were influenced by their environments.

After moving to British Columbia, Nicholas' interests turned to Indigenous peoples and their involvement with the practice and process of archaeology. In 1997, the edited volume *At a Crossroads: Archaeology and First Peoples in Canada* (coedited by Nicholas and Thomas Andrews) assessed the state of Indigenous-oriented archaeology in Canada in the late 1990s and offered examples of innovative and successful strategies for creating more equitable archaeological practice. This volume was followed by numerous book chapters and conference presentations on Indigenous archaeology (Nicholas 2008), collaborative practice, and decolonizing approaches, as well as an edited volume, *Being and Becoming Indigenous Archaeologists* (Left Coast Press, 2010) with chapters contributed by 37 Indigenous archaeologists around the world, sharing stories of their career paths.

In recent years, a major focus of Nicholas' work has been on intellectual property issues related to archaeology and cultural heritage. His 2004 article "Copyrighting the Past," written with Kelly Bannister, represents the first direct examination of issues concerning intellectual property within the realm of archaeology. In 2007, Nicholas was awarded a prestigious Major Collaborative Research Initiative grant from Canada's Social Science and Humanities Research Council for an international and interdisciplinary research initiative titled "Intellectual Property Issues in Cultural Heritage: Theory, Practice, Policy, Ethics." This 7-year project supports community-based research on a range of emerging heritage issues with the goal of informing practice and policy (see www.sfu.ca/ipinch). Although serving as project director of this major initiative occupies much of his time these days, Nicholas manages to keep up with all of his other interests. While remaining fully rooted in and devoted to the discipline, he has always pushed archaeology slightly beyond its comfort zone to places that foster critical reflection, creativity, and groundbreaking scholarship.

Niemeyer, Hans

Francisco Gallardo
Museo Chileno de Arte Precolombino, Santiago, Chile

Basic Biographical Information

Hans Niemeyer (1921–2005) was one of the founders of contemporary archaeology in Chile and was renowned for his contributions to the field of scientific methodology, geography, and the prehistory of the arid desserts and northern semiarid deserts of the country. However, among his many achievements, he is also considered to be the father of the study of rock art. Niemeyer showed interest in these visual artifacts from the beginnings of his passion for the discipline, in an era where the function of rock art was limited to decorating the covers of conference proceedings and other archaeological publications (Niemeyer 1955). He was a hydraulics engineer by profession, a job which led him to travel to the most significant river basins in the country, from the extreme north to Chilean Patagonia. His vocation as an explorer also allowed him to record numerous rock sites and provide the first Chilean rock art panorama at an international level, despite his colleagues' failure to understand the archaeological value of such kind of evidence.

Major Accomplishments

Niemeyer discovered and recorded important rock art sites in the eastern valleys, in Tarapacá, the Atacama Desert, the semiarid north, the central zone, and the Aysén region in the extreme south of Chile. His contributions were not limited to recording as his work also served to establish analytical descriptions, taxonomies, quantitative methods, and the referential styles and interpretation of these visual forms. After 25 years of arduous work in the field, he formulated the first styles by which he organized the enormous range of rock art varieties known for that era.

Although his styles appear governed by monothetic rules, he included other motifs in accordance with the rule of association, a task which allowed him to offer intuitive polythetic classifications. Among these styles several stand out, including the style of *Sierra de Arica* (extreme north of Chile), with its paintings of schematic hunters and naturalistic llamas; the *style of Guaiquivilo*, the fitomorphic engravings, animal and human footprints, and symmetrical figures and curved outlines of which extend widely through the Andean foothills of central Chile (Niemeyer and Weissner 1971; Niemeyer 1972); the *Aconcagua style* with its stylized human figures and subcircular outlines referred to as "signo

escudo" (shield sign) (Niemeyer 1964); and his contributions to the Patagonian style characteristic of the South American cone (Niemeyer 1976). The most traditional were the definitions of the *Limarí style* of faces or masks recorded in the semiarid north of Chile (Niemeyer 1979) or the *El Médano style* (coast of Antofagasta), where we observe extraordinary scenes of trawling whales and other marine mammals (Niemeyer 2010).

Niemeyer worked on rock art right up until a few days before his death. Completely blind, and suffering from a lung condition, he worked on his final and most precious work, the rock paintings of the marine hunter-gatherers of Taltal, of the coastal mountain range of Antofagasta (Niemeyer 2010). He passed away before seeing his book of the "El Médano" paintings published, but he completed the task he considered his primary responsibility: to suitably pass on the fruits of his labor.

Nkang: Early Evidence for Banana Cultivation on the African Continent

Christophe Mbida Mindzie[1] and Luc Vrydaghs[2,3,4]

[1]University of Yaoundé, Yaounde, Cameroon

[2]CreA–Patrimoine ULB, Free University of Brussels, Brussels, Belgium

[3]Research Team in Archaeo- and Palaeo- Sciences (ROOTS), Brussels, Belgium

[4]Centre de Recherches en Archéologie et Patrimoine, Université Libre de Bruxelles, Brussels, Belgium

Introduction

The site of Nkang (11°19′E; 4°16′N) is located about 10 km east of Monatele, in the Lekie division, and 70 km to the northwest of Yaoundé, Cameroon. It is one of the most northern sites belonging to a group of large Stone to Metal period large settlements recorded in the Yaoundé area.

Excavations at Nkang exposed 11 pits as big as 3–15 m^3 volume. They were clustered and spaced some meters intervals and apparently were not linked to any other archaeological features. These pits were originally dug as wells, which were then filled in with refuse following

abandonment. The pits contain admixed soils with broken ceramics, stone tools, iron slags, charcoal, seeds, and faunal remains.

The chronology of Nkang is based on eight radiocarbon dates on charcoal samples recovered from six pits. Three samples recovered from pit F9 were radiocarbon dated between 2850 and 2300 cal BP (800–350 cal BCE with a 95% level of confidence).

Definition

After a comparative study of the volcaniform phytoliths from modern reference samples of *Musa* species and the two endemic African *Ensete* species (*E. ventricosum* and *E. Giletti*), archaeological volcaniform phytoliths recovered from two pits (F9 and F7NF) at Nkang have been positively identified as deriving from *Musa* (Mbida et al. 2001, 2006). Based on the modern-day distribution of bananas on the African continent (De Langhe et al. 1996), they are assigned to plantain. These volcaniforms were recovered from soil sediments (F9 and F7NF) and in a carbonized organic crust adhering to a potsherd (F9).

Two Musa species, *Musa acuminata* and *M. balbisiana*, played a key role in a complex domestication process that involved intra- and interspecies hybridization and plant translocation and ended in polyploidization, seed sterility, and parthenocarpy. Given that the wild ancestors of the African bananas are not native to the continent, any archaeobotanical find of *Musa* means some form of (proto) agricultural or agricultural practice. Based on modern-day distribution of bananas (De Langhe et al. 1996), any archaeobotanical evidence for Musa sp. in the West African context indicates the cultivation of AAB plantains.

The evidence for plant food production during the 3rd millennium BP is in agreement with the recovering of bones of domesticated sheep and goat from other pits features (Mbida et al. 2000) assigned to the same occupation period as the banana phytoliths.

The archaeo-environmental reconstruction for the site is a mixed of primary, pioneer, and old secondary forests and Savannah settings. This is consistent with climatic phase Kibangian B that started around 3000 years ago and would have caused a retraction and fragmentation of the forested habitats and a possible lengthening of the dry season (Mbida et al. 2006).

Plantains are edaphically much more demanding than other banana cultivars and require easy access to nutrients. The older deposits within the pits at Nkang are enriched in organic matter, carbonate, and phosphate. Usually, such refuse dumps are located in the backyards of houses and close to settlements. Thus, the archaeological contexts of the phytoliths along with the edaphic and likely paleoenvironmental conditions are all highly suggestive of plantain cultivation in backyards close to settlements, rather than in forest clearings (Mbida et al. 2006).

The findings at Nkang pertain to four major questions in African prehistory (Neumann and Hildebrandt 2009):

- Early contacts between Africa and Asia
- The contacts and exchanges between coastal African and the central part of the continent
- The antiquity of exotic crops in Africa
- The role of banana cultivation in the spread of Bantu-speaking farmers

Key Issues/Current Debates/Future Directions/Examples

Recently, the original morphological criteria used to distinguish *Musa* and *Ensete* volcaniforms have been revised and confirmed (Perrier et al. 2011). These criteria enable the chronological framework for the domestication, evolution, and diffusion of banana cultivars to be anchored, namely, between 6950 and 6400 cal BP at Kuk, Papua New Guinea (Denham et al. 2003), and

2750–2300 cal BP at Nkang, Cameroon (Mbida et al. 2001, 2006).

So far, the Nkang findings have not been replicated at other sites in Africa. Claims for *Musa* phytoliths at Munsa (Uganda), putatively dated to c. 5000 years ago (Lejju et al. 2005; Leju et al. 2006), are inconclusive due to problems of chronostratigraphic integrity and phytolith identification. More recent archaeological investigations in southern Cameroon for slightly more recent periods (c. 2400–2200 years ago) substantiate a food production system based on Savannah cereal crops (*Pennisetum glaucum*) in combination with the exploitation of plant resources from primary forests (Neumann et al. 2012). The Savannah cereal component was only possible in southern Cameroon during a drier paleoclimatic event starting around 2500 years ago, likely postdating the bananas at Nkang, that resulted in forest fragmentation and a more marked seasonality. To date, the Nkang findings have not been corroborated by archaeobotanical evidence from other sites in the region.

Noël Hume, Ivor

Charles C. Kolb
Division of Preservation and Access, National Endowment for the Humanities, Washington, DC, USA

Basic Biographical Information

An accidental, mostly self-taught archaeologist, prolific writer and one of the founders of historical archaeology in North America, Ivor Noël Hume (known as Nöel) was born in London on November 4, 1927. He studied at Framlingham College and St. Lawrence College in England, spent a brief period in the British Army, and was an assistant stage manager at a London theater. In 1949, he began his archaeological career, joining the staff of London's Guildhall Museum and studying under Adrian Oswald, a pioneer in clay tobacco pipe studies. In 1957, Noël Hume was hired as the first full-time trained archaeologist at Colonial Williamsburg, Virginia, and later became chief archaeologist and director of the expanded archaeology program at Colonial Williamsburg and subsequently the director of the Department of Archaeological Research where he remained until his retirement in 1988. He separated archaeological excavation and laboratory analyses from the Office of Architecture and instituted open-area stratigraphic excavation with grid squares and balks replacing narrow trenching and test pitting done by his predecessors. In addition, he introduced meticulous excavation with trowels and other hand tools (rather than using shovels) and the systematic retrieval and documentation of features and artifacts. This allowed researchers to understand the relationships of buildings to one another and reconstruct Williamsburg's cultural and social history. Hence, the archaeology practiced at Williamsburg is essentially the model for historical archaeology and interpretation practiced today.

Major Accomplishments

His publications, academic and public lectures, and television appearances popularized archaeology and wedded colonial history, archival research, archaeological excavation, and material culture studies into the discipline of historical archaeology. He is a fellow of the Society of Antiquaries of London and served as vice president of the British Society of Post-Medieval Archaeology. The author of 34 major books, monographs, and excavation reports, Noël Hume's achievements include discovering the first traces of England's failed Roanoke Island Colony, excavations at the seventeenth-century site of Wolstenholme Towne, one of the earliest Virginia settlements after Jamestown, and at Martin's Hundred, where its inhabitants were massacred. In Colonial Williamsburg, he conducted major excavations at the original site of Eastern State Mental Hospital, the James Geddy House and Shop, and rigorously documented site evolution at Weatherburn's Tavern. Three Colonial Williamsburg Foundation reports in 1969 focused on glass, pottery, and porcelain; others included the Weatherburn Tavern, English Delftware (1977), and an array of artifacts (1996, 2005), as well as the excavations at Carter's Grove (1974) and Martin's Hundred (1983). In retirement, he directed an excavation (1991–1992) at the Fort Raleigh National Historic Site on Roanoke Island, North Carolina, and located Thomas Harriot's 1585–86 "science center." In 1993, Queen Elizabeth II of Great Britain recognized his achievements, and he was made an Officer of the Order of the British Empire (OBE) for service to the British cultural interests in Virginia.

A majority of his fieldwork and artifact studies were undertaken with his wife of 43 years, Audrey Baines (1927–1993); the couple was childless. In 1994, he married a close friend and colleague, Carol Grazier, and suddenly had a family of four

Charles C. Kolb has retired.

stepchildren (sons Michael and David Grazier, daughters Andrea Zecca and Kristen Welch, and nine grandchildren). Kristen was with Noël Hume when he died following a brief illness on February 4, 2017. He lived in Williamsburg until his passing, writing plays and film scripts, publishing on archaeological topics, and contributing to the *Colonial Williamsburg Journal* and annual *Ceramics in America*. In his posthumous final publication, "A New Bloome" (*Ceramics in America 2016*: 226–237) Nöel Hume rewrote the story of the John Bloome's pearlware puzzle jug dated to 1798 initially published in *Ceramics in America 2014*: 2–18. He reinterpret the polychrome painted decoration of the ship, orthography (Bloome = Bloom), and redated the jug to 1797 – demonstrating meticulous research, candor, and wit.

An interview with Miller (2011) and 350-page autobiography *A Passion for the Past: The Odyssey of a Transatlantic Archaeologist* (2010) is significant, enlightening resources. The original manuscript for this book, "Uneasy Stages: the Making of an Unconventional Archaeologist" (654 pp.) was reviewed for the Director of the University of Virginia Press in September 2008 by Charles C. Kolb – some materials from it are used in this entry.

Nomads in the Near East

Steven A. Rosen
Archaeological Division, Ben-Gurion University of the Negev, Beer-Sheva, Israel

What Are Nomads?

Pastoral nomadic societies are generally defined as those human groups engaged in herd animal husbandry as a primary economic activity and by the consequent need to migrate seasonally to support those herds. Nomadic herders have been a ubiquitous feature of Near Eastern landscapes since prior to the beginnings of recorded history. The mythologies and stereotypes surrounding these groups, originating in the earliest times and continuing through the modern era, are present in histories, literature, film, and nowadays, on the internet. They are primarily those of the noble savage, the primitive, proud, and independent nomad, living off his (and the gender is part of the myth) herds, raiding, and posing a constant threat to the well-being of civilized urban and sedentary society.

Of course, the myth is the result of processes of othering which created a basic bipolarity in perceptions of Near Eastern societies. In fact, nomadism in the Near East comprises a complex and variegated set of adaptations to a mosaic of physical environments, social ecologies, ethnicities, technologies, and changing historical circumstances. Usually defined on the basis of the underlying commonalities of keeping herds and seasonal residential mobility, mobile pastoralists (also pastoral nomads, Bedouin, nomadic herders, nomadic pastoralists, transhumants, etc.) are ubiquitous even today on the landscapes of the Near East, from Baluchistan through Libya, and beyond, well evident in the iconic black tent (Fig. 1), the classic, if not exclusive, mode of nomadic residential structure.

Analytically, Near Eastern nomads are usually contrasted on the one hand with sedentary farming systems (and attached urban systems) and on the other with hunter-gatherers (e.g., Cribb 1991; Khazanov 1984). Stereotypically, traditional ethnographies have thus emphasized the polarity between the settled and the nomad and between farming and herding; in complement, early histories and ethnographies stripped nomadic societies of chronological context and dynamism, placing them in some fossilized social evolutionary limbo between the "primitive" band level societies and more "civilized" chiefdoms and early states. Anthropology in the past 50 years has challenged the essentialist distinctions between farming and herding, and between the settled and the nomadic, emphasizing the spectrum of behaviors along the two axes, farming versus herding and sedentism versus mobility. Archaeology in the past two decades has demonstrated the cumulative and dynamic nature of pastoral and nomadic adaptations in the region over the past ten millennia (Rosen 2017).

Nomads in the Near East, Fig. 1 Typical black tent south of Rajif in southern Jordan Highlands, 1998. (Photograph courtesy of BA Saidel)

As implied by the various names assigned to the phenomenon, pastoral nomads (also nomadic pastoralists), mobile pastoralists, nomadic herders, etc. are characterized by ownership of herds and mobile lifestyles. Cribb (1991) defined the phenomenon by presenting two axes of variability, the one from sedentism to great mobility and the other from full-time practice of agriculture with very few herd animals to no agriculture and general dependence on herds. Mobile pastoralism (a term less laden with preconceptions) is perceived as falling at the far end of the axes, albeit drawing lines defining the edges of the phenomenon is not practical.

Variability in Nomadic Societies in Recent Times

Any discussion of recent nomadic pastoral societies must begin with the tremendous variability inherent between the societies classified as such. Although various analytic typologies have been suggested to describe this variability, any understanding must begin with the great environmental contrasts evident in the vast territory of the Near East, extending some 3000 km from the Zagros to central Libya (Fig. 1), and a roughly equal distance from Turkey to South Arabia, defining the Near East as a unit very loosely so as to include the modern social groups often linked together under the rubric "Bedouin." Thus, the mountain ranges of Iran and Turkey include peaks over 5000 m in altitude, with intermontane basins and plateaus 2000–3000 m high; these contrast markedly with the desert plains of Arabia, Syria, and the Sahara; the Mediterranean zone around the fringes of the Mediterranean Sea offers a forested and parkland zone mosaic of environments, and the riverine valleys and plains of the Nile and Mesopotamia contrast again in basic environmental parameters. Associated with this great range of physical geographic variability, climate and environments in different regions vary greatly as well. Thus, the Saharo-Arabian deserts, beginning just south of the Mediterranean Sea in Africa, and extending eastward into the Arabian Peninsula, nowhere receive more than 200 mm of rainfall per year, and for the most part rainfall averages less than 150 mm, and in many places, in the Rub al-Khali (the Empty Quarter) and in the Central Sahara, yearly average rainfall may be less than a centimeter. However, in the higher mountain areas, rainfall may achieve 1000 mm or more,

and the Mediterranean coastal areas, the Indian Ocean coast of South Arabia, and the Anatolian and Iranian Plateaus commonly average between 400 and 900 mm per annum. With the exception of the southern regions, subject to summer monsoon rains from the Indian Ocean, rainfall is restricted to the winter months, falling almost exclusively between October and April, and primarily between December and March. Temperatures vary with altitude and latitude. Thus, temperatures in the higher areas, in Anatolia and Iran, average roughly between 7 °C and 10 °C; in the Mediterranean zones, between 15 °C and 20 °C; and in the more southern desert zones, between 20 °C and 30 °C. Seasonal and diurnal variation are considerable as well. Vegetation communities, and vegetation cover, correlate with these climatic and environmental attributes. The coastal areas are characterized by Mediterranean vegetation, open parkland grading into Mediterranean chaparral and maquis, succeeded by Irano-Turanian steppe vegetation, and in turn, by Saharo-Arabian vegetation communities. The drier, the less plant coverage. The better watered regions show mixed forest vegetation, although the highest regions may be above tree lines and dominated by shrubs and grasses. The riverine areas, especially the Nile and the Tigris and Euphrates basin, offer permanent running water sources, the Nile characterized by broad leaf vegetation and Mesopotamia by temperate grasslands. The deep deserts, the central Sahara or the Rub al-Khali in Arabia, show sparse vegetation at best, usually only along the wadi courses.

At its most basic level, this environmental variability correlates with basic structures of pastoral mobility in the Near East. Thus, for example, in Cyrenaica, tribes are organized altitudinally, with sedentary farming segments occupying the northern, higher and well-watered zone, sheepherders and goat herders exploiting the steppe zones on the southern slopes, and camel herders inhabiting the deeper desert zone. Each group is affiliated with the same overall tribe but occupies different ecological niches. Seasonal movements tend to be north-south, generally on the order of less than 100 km round trip and perhaps 200–300 m altitudinally, exploiting the different environmental zones in the different seasons. The extreme vertical nomadism of Zagros pastoralists is another example of adaptation to specific contrasting environments, with groups such as the Basseri, the Lurs, and the Bakhtieri moving herds of sheep upward of 1000 m in altitude and 600–800 km in distance (round trip) into the higher mountains with the spring thaw to exploit montane pastures in the summer, and descending to the lowlands in the winter to avoid winter snows and make use of winter rain fed pastures. This type of vertical nomadism, exploiting the environmental contrasts offered by altitude, is complemented by horizontal nomadism (cf. Johnson 1969), exemplified by such groups as the Ruwallah, in the north Arabian and Syrian deserts, and the al-Murrah, in central Arabia and the Rub al-Khali. Seasonal migrations of these camel nomads sometimes extended to greater than 1000 km round-trip, the ecological contrasts required for seasonal pastures afforded only over large and usually north-south expanses. In the Mediterranean zone, such long distance migrations are often not necessary, and migrations may be on the scale of less than 100 km round trip.

Beyond the direct impact of environmental variability on patterns of mobility, the species of animal herded, and indeed subspecies, may be influenced by environment. Thus, camel predominate among the deep desert nomads, whereas sheep are the most common herds in the mountainous areas of Iran and Turkey, and different subspecies of domestic sheep are present in different environments of Iran. Sheep and goat characterize the herds of the Mediterranean desert fringes. Although perhaps a component in some early herding societies, cattle play little role in modern Near Eastern nomadic communities, presumably because they are ill-adapted to the marginal zones inhabited by recent nomads. Agricultural practices may also be determined by environment. Opportunistic agriculture cannot be practiced in the arid zones (except in special microenvironments), but in the Mediterranean zone and along its margins, Bedouin groups have often taken up farming, either as a supplementary practice or in the course of longer term sedentarization. As per Cyrenaica, tribal organization may be attached to environmental patterns and consequent subsistence practice.

Furthermore, environment in the Near East is not a static background to which societies adapt and stabilize. Climatic and environmental change requires constant adjustment by all human groups. Such major environmental trends as the desiccation of the Sahara and the disappearance of Arabian lakes had large impacts on nomadic adaptations, resulting in ever changing patterns of mobility, the exploitation of herds, and relations with the settled zones. Smaller scale environmental change, such as shifting water courses, local salinization, minor shifts in rainfall patterns, and the disappearance of local springs, each affected local and regional histories as well. Thus, historical variability must be greater than that which is evident in modern day societies.

If in some sense environmental variables indeed lie at the core of the need to migrate seasonally (in the Near East, in search of pasture or water), recent mobile pastoralism cannot be reduced to a mere function of environment; economic, social, ideological, political, and technological factors, both internal and external, play major roles in the structure and dynamics of recent nomadic societies in the Near East. That is, pastoral nomadism is not a primitive and autonomous subsistence system, and in the Near East, nomadic groups are tied inextricably to modern markets and to local and regional politics, of course varying with social, economic, and political geographies. Thus, for example, the sale of pastoral products to urban markets, especially meat and wool, relies on market demand for specific products often defined by fashion (e.g., specific types of wool) and taste (e.g., lamb vs. mutton), or political exigency, as in the military alliances between tribes and the British during the First World War. Market demands directly influence, for example, migratory behaviors in the timing of arrival to market and the specific choice of market. Local political constraints can also directly affect migrations, for example, in the need to negotiate right-of-ways through farming zones. Such external relations may effect fundamental changes in power relations within tribes as larger political powers impose leaders of their choice, or indeed necessitate and facilitate the creation of larger scale power hierarchies. Modern technologies, such as guns, automobiles, and irrigation from distant sources, also have had tremendous impacts, changing power relations, as for example in the Arab Revolt during the First World War, or impacting local environments, as in the extinction or near extinction of many native species with the introduction of the gun. In many places, environmental degradation, desertification, can be directly attributed to pastoral overgrazing in marginal areas, but overgrazing should only be seen as a proximate cause; such underlying factors as the imposition of modern borders across extensive grazing areas and rapid population growth resulting from partial sedentarization, increased prosperity and access to modern medicine and technologies created the pressures resulting in overgrazing (e.g., Thomas and Middleton 1994). The low populations of premodern desert populations, combined with the absence of technologies of mass environmental impact, suggest ancient herders had much lesser impacts on their landscapes than modern groups.

Populations of nomadic groups in the Near East grew tremendously in the twentieth century, creating fundamentally new social contexts, not comparable to earlier times. Between the economic impacts of modern global markets on the Near East, the impact of modern medicine on mortality rates, the imposition of state authority on previously tribal areas, and, as earlier, the imposition of modern borders on previously open areas, processes of sedentarization accelerated, all resulting in a demographic explosion. For example, Bedouin in the Negev, Israel's southern desert, increased from an estimated 55,000 in Late Ottoman times to 70,000 just before the founding of the State of Israel, to well over 200,000 in the region today. The impact of this population growth on all other aspects of Bedouin life was tremendous, not least resulting in serious overgrazing (caused also by constraints on grazing caused by modern borders) and land degradation. Processes of rapid sedentarization and acculturation have often resulted in strained relations and conflicts between the state and the tribal societies.

Imposing analytic order on such variability, researchers have also noted common themes (beyond nomadism and pastoralism). Islam has

been the virtually exclusive religion of nomadic groups for several centuries, the last Christian Bedouin having died out several centuries ago. In this, patterns of gender organization (e.g., the segregation of women's quarters) and standardized ritual, for example, in open-air mosques, are common. With few exceptions, Near Eastern nomadic societies are dominated by patrilineal segmentary political organization. The Tuareg offer an exception but are also beyond the geographic expanse dealt with here (Murphy 1967). Tapper (1979) has suggested that apparent modalities in organizational levels (reflecting levels of segmentation) are the result of human biological constraints. Ideologically, most Near Eastern nomadic groups profess egalitarianism as an ideal, but differences in status between lineages at various scales are common. Leadership is thus partially ascribed since leaders will not originate in lesser lineages, but power is not absolute and leadership must be established and maintained.

Finally, the dynamics of nomadic societies are such that there is constant movement between nomadism and sedentism. Barth (1961) described two pathways for individual shifts between these states, poverty and wealth. Nomads who lose their herds often become settled wage laborers, while those who accumulate wealth usually invest in land. Larger tribal scale shifts may occur as groups gain access to arable lands, often through geopolitical processes, and slowly sedentize in the shift to farming. In recent times, nation-states have actively encouraged and sometimes forced sedentarization. Archaeologically and historically tracing these shifts can be methodologically difficult.

Ancient Nomads

Sources for the Study of Ancient Nomads

Analytic approaches to the study of ancient herding societies have tended to focus on origins, the appearance of the first pastoral nomads, thus emphasizing the distinction between nomads and other societies, especially in the Near East. If modern ethnography has blurred the discrete lines between pastoral and agricultural economies, those lines are even more blurred when looking at the evolution of these societies. There is no point of origin, but rather a long and dynamic process of adaptation as different herd animals were adopted into desert societies, exploited for different purposes, the strategies for exploitation shifted, and as those desert societies continually evolved into new forms. Thus, in addition to the variability outlined for modern pastoral societies, one must consider the additional variability of such societies over the course of millennia and the causalities behind this dynamic variability. The study of this variability derives from three basic sources for examining nomads in the past: (1) modern ethnographies, (2) ancient texts, and (3) the archaeology of these societies. Each requires its own critical approaches, offering both important data sets and insights, but also significant pitfalls. Furthermore, the spatial and chronological distributions of these sources are uneven (Table 1). If we have ethnographies of nomadic groups from all over the Near East and North Africa, the historical sources and archaeology are subject to the vagaries of the ancient writers' interests and the preservation of those texts, and to the different developmental trajectories of archaeological research in different regions.

As above, if ethnographies and ethnohistories offer us a profound understanding of the modern adaptation that we call mobile pastoralism, they are also limited in time depth and reflect modern contexts. Thus, such themes as the impact of geographic constraints, the significance of relations between the desert and the sown, general strategies of herd management, etc. may have general relevance for the study of ancient nomads, and such data as the biological requirements of domestic goats and sheep (or camels, donkeys), their genetics, etc. (e.g., Zeder et al. 2006) may be more or less directly applicable to all such animals. Nevertheless, recent and subrecent nomadic societies are firmly embedded in the modern world and cannot be simply grafted onto ancient times. As is true with all ethnographic analogy in archaeology, the ideas and paradigms deriving from modern groups should be conceived of as hypotheses and must be examined in the light of

Nomads in the Near East, Table 1 Chronological chart of absolute chronology, major periods, processes, features, and events reviewed in the text. Dates are approximate

	Periods	Notes	Evidence and geography
			Recent ethnography, history
1000 CE	Islamic		
		Islam	Camp sites, Eastern Desert Egypt Southern Levant
0	Classical	Rome/*Limes Palaestina*

			Eastern Jordan campsites
7000 BCE		Diffusion of domestic Goats/sheep to peripheries	
8000 BCE	Early Neolithic	Goat/sheep domestication in settled zone	Tepe Ganj Dareh (Iran), Near Eastern Neolithic villages

the texts and archaeology of ancient nomads. The great impact of modern contexts can be seen in a range of subjects, including technology, demography, size of markets, and shifting physical and social geographies.

A few examples will suffice to indicate the impact of modernity on nomadic adaptations and to indicate why we cannot simply graft models generated from ethnography onto the past. The introduction of the gun into Bedouin societies into the late eighteenth and nineteenth centuries affected the balance between settled societies and the nomads, rendering tribal societies a greater threat and requiring much greater response by the state; the unconstrained use of guns brought to extinction such species as ostriches, onagers, deer, and oryx and drastically reduced populations of gazelle, ibex, and various predators, changing basic ecologies; it affected hunting and raiding strategies, and Saidel (2000) has noted that even the transition from matchlock to flintlock rifles changed raiding strategies from sedentary ambush to mounted raids. The introduction of tobacco in the sixteenth and seventeenth centuries is one example of the qualitative changes in external relations, with Bedouin groups importing not only the tobacco in large quantities from distances greater than common in earlier periods, but also importing the pipes with which to smoke it. The introduction of petrol powered pumps, installed on refurbished wells from abandoned sedentary settlements, offered new sources of water, deep in the desert, with obvious impacts on tribal distributions and the ability to practice agriculture. In general, the presence of ruins, dating especially from the Classical Era, including cisterns, wells, agricultural terraces, silos, threshing floors, and various buildings, also offered infrastructures for modern nomads not available to ancient groups, especially as concerning run-off irrigation agriculture practiced by many Bedouin groups in the early twentieth century in the southern Levant.

In contrast to ethnography, ancient texts offer contemporary perspectives on the nomads of the time. There are a large number of texts relating to nomadic groups in the ancient Near East, offering invaluable information deriving from such documents as treaties, travelers' accounts, trade records, military accounts, literary texts, and conquest lists. Major sources, for example, include: (1) the Mari texts, deriving from the mid-second millennium BCE archives at the city of Mari on the middle Euphrates with over 400 texts directly concerning tribal groups (Kupper 1957; Rowton 1974, 1977), (2) Classical period travelers' descriptions of nomadic groups and events involving them such as those discovered in the archive at Santa Katerina in South Sinai (Mayerson 1994) or recorded in classical texts such as Herodotus, Diodorus of Sicily, Strabo, and others, (3) a range of late second and early first millennium BCE Egyptian inscriptions describing the extra-urban Shasu pastoralists, (4) Arab histories such as that of Ibn Khaldun, reflecting perceptions of nomads in the Middle Ages, and (5) various early literary texts which may reflect aspects of non-urban societies, such as Gilgamesh. The Bible also contains information concerning tribal groups, although it has been reworked significantly and deciphering its historicity is a complex problem. In general, the texts provide glimpses of great detail into aspects of nomadic lifeways, data not available from other sources, and specific to regions and periods.

In terms of the chronological and spatial distributions of ancient texts, it is obvious that texts do not exist for the prehistoric periods, thus fundamentally limiting historical investigations to later periods. Geographically, pre-Classical period texts are limited to those derived from Mesopotamian and Egyptian sources, which vary considerably chronologically. Thus, for example, the Mari archives offer a depth of perspective on second millennium Syrian nomads unavailable from any other sources. In contrast, although the Nabateans have been viewed as quintessential nomads, our sources for their nomadic origins are restricted to single paragraph in Diodorus of Sicily, recounted from Hieronymus of Cardia writing some two centuries earlier.

The problems of the texts are the standard problems of historiography. The issue of bias may be especially acute since the nomads were rarely literate and the texts reflect the perspective of the settled peoples almost exclusively. Among the Egyptian inscriptions, descriptions of nomads may be recycled from period to period; often the everyday relations between desert and sown are not evident and the texts reflect the conflicts, which constitute news. The Nilus Narrative offers the dramatic account of a nomadic raid on monastic settlements in South Sinai and recounts the kidnapping of a youth, his father's search for him, and his ultimate rescue; Mayerson (1994) compares the story to one from the Wild West but claims it reflects basic underlying tensions between tribal groups and the state. This may be true, but it is fundamentally incomplete in the absence of the daily peaceful relations that obtained. The Blemmyes, putative nomads of Classical Egypt (Dijkstra 2012), are described by Strabo as headless, their faces embedded in their chests, perhaps a reflection of hooded robes, but regardless clearly undermining the reliability of the source. The third millennium BCE Amorites described in Mesopotamian sources as eaters of raw meat is clearly intended as a pejorative (e.g., Porter 2012 for discussion of Amorites as nomads).

The archaeology of mobile pastoralists in the Near East (and for that matter, elsewhere as well) is a relatively young subfield, both within the general study of pastoralism and within archaeology in general (e.g., Bar-Yosef and Khazanov 1992). Although traditional archaeology in the Near East has tended to discount the potentials of the discipline for analysis of past nomadic societies, prehistoric archaeology has long studied small mobile groups in the deep past. The apparent myopia of Near Eastern archaeology is a matter of methods for certainly the study of small herder groups cannot be based on field or analytic methods appropriate for study of massive fortifications, temples, palaces, cities, or even sedentary villages. The very ability of archaeologists to even identify small encampments has been questioned, and when they are identified, archaeologists accustomed to digging large sites often cannot

see the potentials in their analysis (Rosen 2017). To offer an example of the contrasts that may exist between sedentary and nomadic sites, the ceramic assemblage from the nomadic encampment of Nahal Tsafit in the north central Negev, date to ca. 4000 BCE, contained only 18 diagnostic sherds (and only 254 body sherds). The assemblage from the contemporary village site of Shiqmim, about 50 km northwest, contained over 3000 diagnostic sherds. The study of such small assemblages requires different approaches.

More to the point, in the past several decades, pastoral campsites have been increasingly recorded by researchers more attuned to the demands of an archaeology of mobile pastoralists. These sites, their distributions, architecture, material culture assemblages, and other remains (bone assemblages, botanical remains, micro-archaeological analyses, etc.) offer a vast new data set barely tapped in the study of ancient nomads. The archaeological remains clearly complement and supplement materials from ethnography and text history; in particular, they offer perspectives on societies with little or no historical imprint, sometimes predating historical records, and in other cases, providing substance to the scant mentions in the histories. No less important, the archaeological materials greatly expand the range of variability present in the ethnographic record, for example, to societies predating the domestication of the camel, or for that matter, of pack animals in general.

The problems of the archaeological record of pastoral nomadic societies are those of prehistoric archaeology. The record is very much a function of where research has been conducted, at what level of intensity, and in what environments. Thus, the deserts of eastern and southern Jordan, the Negev, and Sinai have provided the greatest amount of archaeological data on early nomads, a result of both intensive archaeological research and the desert environment in which sites are readily visible during pedestrian survey. In other regions, small campsites may be buried under alluvium, near invisible due to vegetation, or destroyed by agricultural practices and other development. In light of the very recent development of interest in the archaeology of nomads, the political constraints of working in recent decades in the Near East have also resulted in a patchiness to the record.

Conceptually, unlike traditional Near Eastern archaeology, it is hard to tie pastoral encampments to political histories or to specific events of the historical record. Unlike the tells of Near Eastern archaeology, which come with modern names and can often be identified with specific ancient sites, campsites reflect general process and can rarely be securely identified with places or peoples. That is, the questions to be asked of the archaeological record of mobile pastoralists differ from those usually addressed to the archaeology of sedentary societies. Nevertheless, the potentials for new perspectives and new insights from this almost untouched aspect of the archaeological are great.

Domestication and the Earliest Herding Societies in the Peripheral Zones

The domestication of goat and sheep, on which the earliest herding societies were based, occurred within the contexts of settled Early Neolithic cultures in the Near East. In the hilly flanks of the Fertile Crescent, along the edges of the Zagros and Taurus Mountains, the transition from hunting wild goat (*Capra aegagrus*) to herding domestic goat (*Capra hircus*) can be traced over the course of the ninth millennium BCE (Table 1), most notably at the site of Tepe Ganj Dareh, in northwest modern Iran, an early Neolithic village (Zeder and Hesse 2000). There are crucial datum points to be emphasized in this transition:

1. Although it is trivial to note, goats were not domesticated at some single point source. Goat hunting occurred over a large expanse of the northern and eastern highlands of the Near East (the apparent core areas of wild goat distribution). The evolution from hunting to herding probably occurred over this entire expanse as technological and social trends diffused rapidly within a similar cultural matrix. If Tepe Ganj Dareh is taken as a point source, it should be taken that way only for heuristic purposes.
2. The agents of domestication were sedentary village farmer-hunters. This contradicts earlier assumed evolutionary sequences based

essentially on racist notions of cultural sophistication drawn from nineteenth-century ethnography and which reconstructed a progressive sequence from hunting-gathering societies to herding societies to peasant farming societies to civilization (e.g., Childe 1951: 20–36). This idea of farmer-hunters, which seemed odd to European conceptions of progress, is well represented by New World farming societies (based on maize), where no herd animals were ever domesticated given the absence of easily domesticated species.

3. The implicit default in many reconstructions of animal domestication, seemingly based on analogy with modern herding societies, that is, the Bedouin, is that these early Neolithic societies had large herds. These herds would presumably have achieved the magic number of 40–50 head per nuclear family, again based on analogy with recent mobile sheep and goat herding societies in the Near East. There is no evidence that these earliest experiments in domestication resulted in herding practices of such large numbers of animals and more critical evaluations suggest barnyard type adaptations where families had only a few animals, kept in close proximity to the family itself, within the confines and immediate vicinity of the villages (e.g., Arbuckle 2014). No evidence for specialized herding facilities has been discovered either within the village sites of the Near East, or outside them, for example, in the form of stabling in rock shelters, corrals, or herding camps (per contra Hole 1974).
4. Assuming a Zagros-Taurus origin of goat and sheep domestication, the idea of herding, and perhaps the animals themselves, spread rapidly throughout the Near East. If the earliest evidence for domestic animals (goats) at Tepe Ganj Dareh dates to the mid-late ninth millennium BCE (and dates are not precise), then certainly by the terminal ninth/early eighth millennium BCE, domestic goats are present as far west as the Levant (e.g., Horwitz et al. 1999). Again, dates are not precise. The rapidity of the diffusion of domestic goats, and shortly afterward if not contemporaneously, sheep, is notable; it indicates that this new subsistence technology, one perspective for looking at the adoption of domesticate animals, was easily integrated into the Early Neolithic village social matrix. Indeed, one sees little immediate impact on architecture or other physical features of the archaeological record such as troughs or corrals. Notably, some Levantine faunal assemblages show a single phase transition from intensive hunting of gazelle to goat husbandry, from 60% to 80% gazelle bones to similar percentages of goat bones in the transition from Early Pre-Pottery Neolithic B to Middle Pre-Pottery Neolithic B (Davis 1984). In spite of this apparently rapid transition, it was not all-encompassing but mosaic in its distribution; some sites continue to show a dominance of gazelle, although by the Late Neolithic, this is no longer the case (Horwitz 2003).

That is, by the early/mid-eighth millennium BCE, sedentary village sites in the Near East had achieved the basic subsistence farming complex that would remain the staple until recent times, including cereals (wheat and barley), legumes (chick peas, sweet peas), some fruits, and sheep and goats. (The cash crops that would characterize Mediterranean agriculture, olives, grapes, and fruits were domesticated only later, in Late Neolithic and Chalcolithic times.) In significant contrast, in the desert and steppe zones later to be home to mobile pastoral societies, complex band level societies whose subsistence was based on hunting-gathering continued to dominate through the end of the PPNB.

This time lag between the adoption of domestic herd animals in the settled zones and in the desert, on the order of 500–1000 years, reflects fundamental differences in the basic adaptations. The integration of goats and sheep into village farming societies seems to have been an adjustment; the transition from desert hunting-gathering to herding demanded fundamental changes in lifestyles. Ingold (1980) explored some of the ramifications of this transition in his study of reindeer domestication among the Lapps, touching on such aspects as contrasts in settlement patterns and ideologies reflecting ownership. Beyond this, if

one considers the necessities of herd maintenance, then in exchange for constant access to the animals, desert herders must provide constant subsistence for them. Ingold importantly distinguishes between ranching, where animals are owned but to a degree autonomous, and herding, where the animals are constantly provided for. It is unlikely that goat and sheep herds were ranched, especially given the environments into which they expanded in the course of their adoption into desert hunter-gatherer societies.

The Transition to Herding in the Steppes and Deserts of the Near East

The earliest clear evidence for an association between seasonal habitation sites and domestic goats and sheep in the peripheral zones in the Near East derives from the eastern desert of Jordan and dates to the PPNC, the first half of the seventh millennium BCE, post-dating the collapse of the mega-sites of the Pre-Pottery Neolithic B (Garrard et al. 1996; Betts 2008). These sites seem to reflect a general continuation of desert PPNB architecture and material culture but show for the first time varying quantities of goat and sheep in the faunal assemblages (Martin and Edwards 2013). That is, there was no immediate adoption of goats and sheep with an abandonment of hunting, but a long and probably rather opportunistic adoption of small numbers of domesticates into these peripheral hunting-gathering societies. The chronology of this adoption, apparently coincident with the collapse of Pre-Pottery Neolithic B social frameworks, most evident in the abandonment of the PPNB megasites, suggests a causal relationship. Certainly the source of the desert domesticates is to be found in the adjacent sedentary societies; however, the mechanisms of transfer and adoption are not clear. Some researchers have suggested that the PPNB collapse is accompanied by a fissioning process wherein pastoral groups split off from their sedentary cousins, expanding into the periphery with their herds (Kohler-Rollefson 1992). Alternatively, the social breakdown of the PPNB collapse must also have affected relations between the peripheral hunter-gatherer societies and their sedentary cousins. It is in this transition to a new social matrix, involving changes in trade relations, value of goods, and social networks, that the adoption of domestic animals into desert societies occurred.

By the end of the seventh and into the sixth millennium BCE, transformations in the proto-

Nomads in the Near East, Fig. 2 Map of the regions and geographic features mentioned in the text. Modern states are italicized

Nomads in the Near East, Fig. 3 Ramon 1 rock shelter (Negev, Israel), showing general view (upper) and east section with accumulated dung layers (SA Rosen)

herding societies of the peripheral zones are evident. Rock shelters (Fig. 2) in the Negev show layers of goat/sheep dung dated to ca. 6000 BCE reflecting stabling of herds of animals (Fig. 3). These dung layers reflect two innovations in herding: (1) the presence of relatively large herds is reflected in the accumulation of dung layers in the rock shelters, a phenomenon seen in recent herding societies as well, and (2) the off-site stabling of animals, away from the actual habitation sites, indicating organization of herding with goatherds/shepherds, beyond the physical association of the herds with family groups. If the chronology of this transformation is correct, then the reorganization of herding practices may be an adaptation to the 8.2 k (6200 BCE) climatic event, a climatic deterioration which may have required more extensive grazing into order to support ever growing herds.

This transformation in herding practices seems to be accompanied by basic changes in the pastoral societies themselves. In the sixth millennium BCE, the following features appear in the archaeological record of the southern Levantine deserts:

1. The basic pattern of campsite architecture shifts from clustered or single round or oval pit houses to enclosure-and-attached-room compounds (Fig. 4). These consist of large round and sometimes irregular shaped enclosures constructed of low walls of fieldstone with small round or oval rooms (sometimes u-shaped) attached around the periphery of the enclosure. Although preserved walls are of stone, they are rarely higher than two or three courses and undoubtedly represent hut bases which had organic superstructures. The enclosures have been invariably interpreted as pens. This shift in architecture thus reflects a

Nomads in the Near East, Fig. 4 Shrine 1 at Ramat Saharonim, Negev (Late Neolithic), aligned with the setting sun of the summer solstice (SA Rosen)

major change in architectural function to serve the more intensive herding of the period.

2. In the mid-sixth millennium BCE, and continuing minimally for hundreds of years if not more, mortuary and shrine complexes appear, sometimes as separate phenomena but often linked. Fields of burial cairns, often with hundreds of large cairns and platforms, have been documented in the deserts of Arabia, eastern Jordan, the Negev and Sinai, and the different variants (e.g., nawamis, tower tombs) have been dated securely from the mid-sixth millennium through the third millennium BCE. Conceptually, similar phenomena are found in the dolmens of Syria, which extend into the southern Levant, but whose chronologies are still disputed. The most common shrines (sometimes referred to as open-air temples) consist of open rectangular or quadrilateral courtyards, typically 8 × 20 m in dimensions, demarcated by small upright slabs around the circumference. The western side of the courtyard is often a massive double wall built of larger blocks which stood about 1.5 m high and was about half a meter thick, with intentional fill between the outer blocks. Variants include an elongate cell with small stelae in the interior, the large western wall without the attached courtyard, and complexes with various additional features (geoglyphs, additional structures), not always contemporaneous. The solstice orientation of these shrines is striking such that a line orthogonal to the massive western wall invariably aligns with the setting sun of the summer solstice, plus or minus a few degrees (Fig. 5).
3. Although rock art is notoriously difficult to date, recent studies in the Negev have constructed a chronology based on superposition of elements within single panels, and on differential patination on different components within single panels (to avoid the problems of variability in patina development). Tying the relative chronology to features within the rock art which may serve as fossil indices (the presence of ridden camels and donkeys, the presence of the compound bow, the presence of specific sword types, inscriptions, etc.) suggests that the earliest systematic and common appearance of petroglyphs is dated to this period of consolidation of herding practices and pastoral society in the region.
4. Desert kites are large animal drive traps, constructed of converging walls, sometimes hundreds of meters in length, with either enclosures or pits/falls at the apex of the converging walls. Walls are rarely higher than two or three courses; they work because the tendency of such animals as gazelle is to avoid jumping over barriers during flight. They reflect communal hunts, strategic planning in their location and in the investment, and probably some kind of ownership or rights of usage. There is still no consensus on dating; although most authorities agree that the peak in use and construction occurred during the fourth and third millennia BCE, there are hints of earlier phases of construction during the Late Neolithic.
5. The material culture transformations following the Pre-Pottery Neolithic are varied, and the trajectories of development in the desert diverge from those of the settled zone. Although pottery emerges in the late seventh millennium BCE in the early stages of the Late Neolithic in the sedentary zone, it becomes common, if not abundant, in the desert only some two millennia later. Lithic functions and technologies diverge as well. If by the end of the sixth millennium BCE chipped stone arrowheads have disappeared from the settled Mediterranean zone societies, they continue in use in the desert at least through the mid-third millennium BCE, most notably in the form of transverse points. The rise of large flake industries in the desert began with Tuwailan bifacial knives, dating to the seventh and perhaps early sixth millennium BCE. This industry was the technological precursor to the tabular scraper industry, wherein large cortical flakes, 10–20 cm in largest dimension, were produced in large numbers and traded into the settled zone in the fifth through third millennia BCE. Although there has been debate concerning the intensity of production of these pieces, there is consensus on their association with desert pastoral societies. Notably, there is no evidence for

Nomads in the Near East, Fig. 5 Enclosure-and-attached-room architecture, Camel Site, Negev, Late Timnian. Reconstruction drawn by H. Sokolskaya. (ca. 3000 BCE)

production of these scrapers, which likely functioned more as knives, in the settled zones. Finally, by the late fifth millennium BCE, copper production begins to play a role in the Ghassulian Chalcolithic culture of the Mediterranean zone. Crucially, the copper sources are present only in the desert zone, and there is increasing evidence that the early mining and trade in copper was undertaken primarily by the pastoral nomadic societies inhabiting those regions.

All told, these innovations and transformations suggest the crystallization of a new social matrix in the desert, one based on the centrality of herding. This is seen most obviously in the transition to enclosure-and-attached-room architecture (Fig. 4). The construction of cairn fields and megalithic ritual sites also reflect social innovations in the desert, suggesting new social functions and needs which can also be linked to the herding revolution. Thus, cairn fields suggest

increased territoriality, especially in their visibility from great distance; the increased territoriality can be attributed to the absolute need to support herds. Both the cairns and the shrines reflect both new levels of labor organization and hierarchy, and public declarations of ideology and cosmology, tools for legitimization of the social order. Similar arguments can be made for the significance of the rock art, in a new symbolic order, the desert kites, in new forms of communal action and ownership, and in the intensification of exchange as reflected in the tabular scraper trade. For the deserts of the southern Levant, this new cultural formulation has been dubbed the Timnian Cultural Complex. The Timnian represents a greater level of social complexity than evident in earlier periods in the desert zones (and it is important to note that discussion is restricted here to these peripheral areas), one which can comfortably be subsumed under the general rubric of tribal society.

The Evolution of External Relations

Anthropological analyses of recent Eurasian nomads have more or less debunked the myth of modern pastoral nomadic autonomy. They have demonstrated repeatedly the dependence of nomadic societies on their sedentary counterparts for a range of goods and services (including the possibilities of tribute, raiding, or conquest to obtain these) or the adoption of sedentary practices such as agriculture, at least part time. On the other hand, as in the previous section, in the earliest stages of the development of peripheral pastoralism, nomadic economies are perhaps best characterized as herder-gatherers and *were* essentially autonomous, with herding essentially replacing hunting. Thus, the issue of when dependence and interdependence between the settled and the nomadic developed is of great interest.

Addressing this issue, by the fourth and third millennia BCE, relations between peripheral nomads and settled society intensified greatly, especially as villages and towns evolved into cities and states, offering goods, services, and markets for peripheral tribal groups. This intensification seems to mark that initial transition to the economic asymmetries that characterize recent relations between nomads and settled societies.

In this context, there are three developments concomitant with the rise of intensified exchange: (1) The development of complex societies, elite consumers, and larger markets in the settled zones, (2) the discovery of and increased demand for goods and materials deriving from the peripheral zone feeding into those complex societies, and (3) the domestication and systematic exploitation of pack animals, facilitating the mass movement of goods. There is clearly an interdependence between these developments. Without pack animals, large quantities of goods would have been more difficult to move through the desert, and without the demand for such goods and materials, the selective pressures which resulted in the domestication of the donkey, and later the camel, would have been of a much lesser order.

The development of complex societies, that is, cities and states, is a prerequisite for conditions of dependence and economic asymmetry. Subsistence level village society, virtually by definition, could not produce the surpluses required to support large peripheral tribal groups, and did not provide the markets to justify significant investment in providing goods and services offered by those groups. Thus, the rise of economic asymmetries and dependence relationships was historically and geographically specific, as complex societies evolved in different chronological trajectories in different regions. Within the Near East, as a more or less integrated region, the chronological variability may be limited, but at the edges, for example, in North Africa, Southern Arabia, or even the Southern Levant, somewhat removed from the evolution of primary states, lag times may be evident.

It is notable that a number of researchers have linked the rise of peripheral pastoral societies specifically to the development of centralized states (Lees and Bates 1974; Sumner 1986). Alizadeh (2010) has proposed that the early states on the Iranian Plateau originated in the crystallization of nomadic tribes as regional political powers. If on the one hand this seems to contradict

received knowledge on the evolution of early states in the region, the relationship between pastoral tribal societies and the Mari kingship, in the second millennium BCE, seems well documented historically (Fleming 2009) and thus should not be rejected out of hand.

Beyond the chronological contingencies, the specifics of the goods and services also vary. Such goods as wool and copper clearly played major roles in the intensification of desert-sown relations. Trade in other goods, such as milling stones and tabular scrapers, also seems to have intensified. One might also make a case for materials less archaeologically or historically evident, such as dairy products and meat, the provision of caravan services, and conversely, protection. Other objects, such as beads, shells, and semi-precious stones, continued to be exchanged between the peripheral and settled zones, but it is hard to see in them reasons for or evidence of intensification.

A few examples illustrate the ideas. Historically, texts from third millennium BCE Mesopotamia indicate the production of vast quantities of woolen textiles in the Mesopotamian heartland, the wool ostensibly originating with tribal groups raising sheep on the periphery of the riverine lands. Although there is circumstantial evidence for spinning of animal fibers as early as the seventh millennium BCE at Tell Sabi Abyad, in northern Syria (Rooijakkers 2012), intensive exploitation of (downy) wool is only dated to the third millennium in Mesopotamia and can perhaps be pushed back to the fourth millennium. Porter (2012) attributes such importance to wool production that she sees the nomads of the period integral to the very development of these early complex societies, to a degree echoing the claims of Alizadeh (2010). Algaze (2009), adopting third millennium economic models, also stressed the importance of woolen textiles (and by implication of sheep herding) for the Uruk expansion. The impact of the increase in demand on the wool producers, the peripheral pastoralists, would have been great.

Copper production and metallurgy, in general, have often been proposed as prime factors in the rise of complex societies, in the need for specialized production, as goods cementing ties between elites, as rare goods symbolizing and legitimizing political hierarchies, as major new technologies, etc. In the Southern Levant, copper sources are located in Wadi Feinan, in modern day southern Jordan, in Timna, in the southern Negev of modern day Israel, and in South Sinai, in Egypt, all three deep in what would have been nomad territories in the fifth and fourth millennia BCE. That is, the involvement of nomads at various levels in the early copper trade, in the late fifth and early fourth millennia BCE, makes geographic sense. Material culture from the sedentary zone, the Ghassulian Chalcolithic, is lacking in the copper source areas, and the agents of mining, trading, and perhaps the production of some artifacts seem to have been the nomads of the aforementioned Timnian Culture. Although ultimately co-opted by various kinds of incursions from the settled zones in the third millennium BCE (trade stations, mining camps), the demand for copper seems to have stimulated settled-nomad relations and nomads continue to be involved in the metal trade through the end of the third millennium BCE.

The general intensification of relations stimulated by one or more factors also facilitated other aspects of trade. Thus, in Jordan, massive numbers of tabular scrapers were produced in the desert and exported into the settled zone; all researchers concur that this was part of the nomad-settled trade system. Similarly, in the Negev, there is ample evidence for nomadic production of milling stones from sandstones available only in the periphery and their trade into the settled zone. Other goods such as beads, shells, and semi-precious stones also moved from the desert into the settled zone. Evidence for intensified dairying (in bones on sedentary sites) in the third millennium BCE suggests a possible market for dairy products from the desert as well. The diversification of nomad economies here, tapping into sedentary markets, in modern times has been dubbed multiresource nomadism. It has early roots.

The impact of the domestication of the donkey cannot be underestimated. Although goats can be loaded with perhaps 30 kilo of goods, and there

are hints in some figurines that they may have been exploited in this way, the domestication of the donkey marks a major increase in the efficiency of overland transport. Donkeys can carry on the order of 80–100 kilo of goods over long distances, over areas where wheeled vehicles could not pass. The transport of heavy milling stones, large quantities of ores or copper tools, or of tabular scrapers was only made possible by the systematic integration of the domesticated donkey into trade systems in the mid-fourth millennium BCE. They were the primary means of land transport of goods in the Near East from their domestication in the mid-fourth millennium BCE until the introduction of the domestic camel, more than 2000 years later. Caravan trade thus becomes a staple of nomadic adaptations, and is reflected in the increased diversity of goods, included heavy and bulk goods, moving from desert to sown very early on. The point here is that none of these processes, the rise of complex economies and societies, the intensification of nomad-sedentary trade, and the domestication of the donkey, are independent. Each provides contexts and feedback loops for the other. In these interrelationships, nomadic tribes prospered, ultimately achieving relationships, economic and demographic, from which there was no return to previous states of autonomy and subsistence.

Social Integration

As earlier indicated, our knowledge of the history of mobile pastoralism is geographically and chronologically patchy. Beyond the southern Levantine deserts, little archaeological study has been conducted of nomadic sites themselves, small campsites, shepherds' stations, larger encampments, etc. However, by the late third and second millennia BCE, historical sources (notably not available for earlier periods) become a prime source of information and understanding of nomadic societies. For the earlier part of this span, the historical references to the Amorites are problematically stereotypical. Similarly, assumptions as to the nomadic nature of the Kura Axes archaeological culture(s) are also based on little beyond speculation. On the other hand, the second millennium BCE archives from Mari, a city state on the Euphrates, contained over 400 texts relating to nomads and offer information on subsistence, settlement, political organization and affiliation, movements, and cultural affiliation. In a series of integrative essays based especially on these archives, Rowton (1974, 1977) defined two types of Near Eastern nomadism, enclosed and external. Enclosed nomadism is that which filled the interstices between settlements in the Near Eastern steppes, beyond the rivers and hills and is tied inextricably to local politics and society, a dimorphic society. External nomadism is that which was to be found beyond the edges of the fertile zones. Indeed, the Mari archives offer the first detailed text-based perspective on pastoral societies in the Near East. There has been little corresponding archaeological research, and there are no parallel texts for earlier periods, rendering comparative analysis of earlier nomadic societies (as in the preceding section) difficult. Strangely, even the archaeological record of the second millennium BCE in the desert regions has been lacking, a source of some debate on the efficacy even conducting archaeological investigations of nomadic societies in later periods.

The Mari archives present a picture of essential integration between the tribal groups and the Mari state. Fleming (2009) connects the very kingship of Zimri Lim to tribal connections. If at one level the state seems to be in constant tension with the tribes, in negotiations with them, on the other, these are not the negotiations conducted with other states but with components of the larger Mari system. The texts, written from the perspective of the ruling powers in Mari, reflect all of the factors which would impact on relations with the state, including the co-option of local leadership, drafting of soldiers, and taxes/payments of various kinds. They indicate also that the various tribes, for example, the *Bani Yamina*, migrated seasonally with their herds, although we have no indication as to who actually moved, the entire population, smaller groups, or only shepherds. At least some of the tribes resided in villages and engaged in agriculture.

It is notable that interpretations of the Mari archives as reflecting nomads reflect the

anthropological and historical concerns of the day. Thus, in the earliest synthetic study Kupper (1957) very much adopted a "struggle between the desert and the sown" approach. Writing a generation later, and in light of anthropological analyses of modern nomads, less polarized approaches were adopted. In the works of Fleming (2009) and Porter (2012), much greater basic political integration is emphasized.

Further texts, deriving from a wide range of sources, also reflect various kinds of extra-urban tribal groups. Thus such groups as the Sagaz, the Apiru (perhaps equivalent of Sagaz), and the Shasu are mentioned in texts from all over the Near East (Bottero 1954; Giveon 1971). These are not ethnic designations but refer to socioeconomic status, perhaps as one might refer to peasants within a specific region. Although the term "Bedouin" has been used, this is to adopt a term with accepted meaning and to thus impose it on groups which probably did not resemble the Bedouin (e.g., no camels until the latest periods of the texts). The Apiru are described variously as extra-urban, nomadic, brigands, mercenaries, but are not associated with pastoralism in the texts. The Shasu, on the other hand, are described in a similar fashion, but also had flocks; one late reference even refers to them as tent dwellers, although they are also indicated as living in villages. The problem with all of these is that the texts offer us only glimpses, small windows of selected facts; it is not even possible, for the most part, to string together a reliable chronology. Eph'al (1984) had summarized much of the literature on the nomads on the fringes of the settled regions in the Iron Age, deriving especially from Assyrian records. We thus have a record of Assyrian campaigns against the marauders, sometimes offering invaluable information on these groups (e.g., the use of frame tents, camels). But we cannot even identify the specific geography of these campaigns.

The introduction of the camel during the Iron Age, in the Near East most especially the dromedary, comprises another step in the cumulative adaptations which characterize recent nomads. We have little reliable information on the initial stages of camel domestication, which seems to have occurred in the Persian Gulf area. The camel is not mentioned in any of the Mari texts, or for that matter any contemporary text prior to the late second millennium BCE, claims for the donkey-of-the-sea as camel notwithstanding (Lambert 1960). However, by the Iron Age, faunal assemblages begin to show camel bones regularly, if not always abundantly. The Assyrians had already integrated camels as pack animals into their campaigns in Palestine, and the desert caravan trade seems to have adopted the more efficient camels over donkeys by the beginning of the first millennium BCE (Sapir-Hen and Ben-Yosef 2013). The adoption of camels into the economic systems of the Near East considerably enhanced all aspects of nomadic society. Camels can carry three times the load of donkeys; they can travel longer distances without water, penetrating into the deep desert. This ability, combined with the rapidity of travel on camel back and the introduction of the North Arabian saddle allowing more effective warfare, also comprise a new threat to sedentary society and to caravan trade (Bulliet 1990). The adoption of the camel sets the stage for the later configurations of nomadic societies, to develop most notably in the succeeding Classical Era.

The Classical Era

The millennium-plus span from the end of the Iron Age through the Early Islamic period, Classical Antiquity, saw the establishment of the premodern configuration of nomadic societies in the Near East. The states of this period offered new markets, at the scale of large states and empires, for adjacent (and interstitial) nomads, and new economic frameworks and opportunities. Examples include the impact of treaties on settlement systems (including payments in exchange for keeping the peace and the co-option of tribes for military service), the employment of nomads as laborers and mercenaries| in sedentary settlements especially in the frontier areas, stock raising for imperial military for both food and transport, and the state construction of such infrastructures as wells, cisterns, and agricultural systems deep in the deserts, affecting nomadic trade and subsistence. Long range caravan trade based on camels became established, either controlled by nomadic

groups or subject to their raids. Together these economic stimuli probably resulted in significant demographic growth and would seem to have effected political changes and the rise of federations of nomadic tribes, constituting more than nuisance threats to the adjacent states. Toward the end of the period, the adoption of Islam resulted in a new set of symbols and behaviors, seen for example in the presence of open air mosques. In fact, in the deserts of the southern Levant, the presence of numerous mosques in association with nomadic encampments suggests early and relatively easy adoption of Islam.

Numerous classical texts describe the relations between nomads and settled peoples in this period, and the archaeology of the Eastern Desert of Egypt and the southern Levant deserts has revealed a general Classical Nomadic Complex (Rosen 2009). Two types of texts offer different perspectives, dovetailing in viewing the nomads as "other." Travelers' and literary accounts describe the exotic aspects of nomadic cultures. For example, the Blemmyes are described by Strabo as headless, with facial features embedded in their chests; travelers' accounts from Sinai describe the miserable state of desert inhabitants' existence, often stressing the hostile aspect of relations. Treaties and histories stress the conflicts between the tribal groups and the state. Mayerson (1994), in a rather traditional view of history as writ large, has characterized the relations between the Roman (and Byzantine) empire and nomadic tribes on the edges of the empire as essentially hostile.

The archaeology of the nomads, as opposed to the archaeology of the state facing the nomads as in the *Limes Palaestina*, offers a complementary perspective. Beginning in the Hellenistic period and continuing through the Early Islamic period, archaeology in southern Jordan, southern Israel, and the Eastern Desert of Egypt documents a new settlement type, consisting of rows of round structures built of field stones, usually along wadi terraces (Fig. 6). These vary in degree of investment, sometimes consisting of proper walls, sometimes only wall bases, and sometimes only the outline of tent bases, the stones marking the cleared areas or the stones used to hold down tent flaps. Aggregate sites may consist of anywhere from 4 to 5 structures up to dozens, and sites with single structures are also known. Site distributions in the Negev and Jordan indicate seasonal movement from the desert zones into the agricultural zones (also in the arid zones, but based on run-off irrigation), with patterns of population aggregation and dispersal.

Chronologically, this nomadic complex seems to begin in the Hellenistic era, with the Nabateans, in the last centuries of the first millennium BCE (according to the texts), or archaeologically perhaps somewhat later. Given only a few excavations, and the difficulties of precise chronology based on surface survey collections, chronological trends in the nomadic system are difficult to reconstruct. There are hints of demographic growth and increasing camp size (for the aggregate seasonal camps) among the nomadic groups on the edges of the empire by the mid-first millennium BCE. These trends probably also reflect changes in patterns of mobility. Certainly, if one accepts the texts at face value, the Nabateans sedentized and formed a state initially based on trade. However, the nomadic complex which seems to have begun with Nabatean nomads did not cease with that transformation, and beyond the settled zones of the Nabatean kingdom, archaeology demonstrates the continued presence of nomads through the second half of the first millennium CE.

Contrary to the picture of hostility obtained from the texts, the proximity of the nomadic systems to the sedentary agricultural systems, including solitary farmhouses, small villages, and towns at the edge of the Roman/Byzantine/Islamic empires, suggests that real threats were rare. In South Sinai, hundreds of monks lived side-by-side with the local pastoral population. The archaeology indicates that over 90% of the pottery found on nomadic sites derived from the settled zone. Other preserved material culture including milling stones, metals, and coins also derived from the settled zone. In the absence of agricultural installations (field systems, threshing floors) in much of the nomadic zone, and given the presence of milling stones, trade in agricultural goods seems likely. Fish bones in the middle of the

Nomads in the Near East, Fig. 6 Classical period (Byzantine) nomadic site consisting of line of round structures, tent bases or hut bases, along wadi terrace. Site 204/70 (p. 57) in Rosen SA (1994) *Archaeological Survey of Israel Map 204, Makhtesh Ramon*. Israel Antiquities Authority, Jerusalem

desert suggest trade in dried fish, also deriving from the settled zone. This would accord with much modern ethnography. In fact, reading between the lines in the texts, economic relations between the nomads and the state include a wide range of links (e.g., animal trade, guides, labor), belying a picture of underlying hostility. In fact, for the nomads on the edge of the empire (although not necessarily for those deep in Arabia), one may posit an economic dependence on the settled zone. Certainly, with the collapse of the settled system at the periphery at the end of the Ummayad period (in the mid-eighth century CE), the nomadic complex collapsed as well.

Final Notes

The study of ancient mobile pastoralists in the Near East is still not yet a mature field of historical or archaeological research. Research has been uneven, both chronologically and geographically. Many historical records have yet to be investigated, and the archaeology of campsites is in its infancy as a subdiscipline. Nevertheless, recent important work from all over the region demonstrates the potentials research on ancient nomads. Several important trends are evident.

The idea that nomads do not leave remains, or at least not enough remains that can be profitably

analyzed, is no longer the default assumption of archaeologists working in the Near East. Recent work in Turkey, Kurdistan, and Iran add significantly to the body of research from the Southern Levant. In the near future we can expect to see historical syntheses of these researches. Indeed, most recently the archaeological exploration of recent nomadic sites offers perspectives on interpretations of ancient sites, but also new insights on nomadic cultures in the past several centuries, insights not available from our ethnographies and histories.

The myths of nomadism no longer dominate the historical and anthropological narratives. Few archaeologists or historians automatically graft the paradigms of the struggle between the desert and sown directly onto the past. In a more nuanced way, although ethnoarchaeology will ever play an important role in archaeological research, the perils of mechanical adoption of recent insights are also understood. There is understanding that nomadic societies have evolved socially, politically, and historically no less than their sedentary counterparts, that modern nomadic societies are not timeless fossils hearkening back to an ahistorical past. The study of that past has much to offer, not only for understanding the historical specifics of nomadic peoples, or even the more complete histories of specific times and places, including the nomads, but for the general understanding of the human condition.

Nondestructive Subsurface Mapping in Field Archaeology

Immo Trinks
Ludwig Boltzmann Institute for Archaeological Prospection and Virtual Archaeology, Vienna, Austria

Introduction

Archaeological *excavation* provides unparalleled detail of past lives, but it is a costly process and destructive to the site under investigation. Cost and respect for the resource means that excavation can only be applied over limited areas. By contrast, subsurface mapping methods can cover wide areas while leaving the site intact (Scollar et al. 1990). These methods, once regarded only as a means of finding sites (prospection), represent now a complementary tool kit for detailed archaeological investigation of a site and its surrounding landscape. The methods provide overviews of human activity and buried structures of archaeological and historical interest in increasing detail over considerable areas. Subsurface mapping also permits the selection of high-potential areas for targeted scientific excavations and provides a broader settlement context for sites already excavated. Recent developments based on high-resolution multichannel near-surface geophysical technology and advances in state-of-the-art remote sensing now permit the cost- and time-efficient spatiotemporal archaeological investigation and documentation of buried features across entire landscapes. This has applications in both research and rescue projects.

Key Issues

The most commonly used ground-based archaeological subsurface survey methods are magnetic, electromagnetic and geoelectric (Gaffney and

Gater 2003). Less frequently employed are geochemical methods, the best known being phosphate mapping. Traditionally *surveys* are conducted manually in rectilinear grids using tape measures and survey lines placed on the ground for orientation and facilitating exact sample positioning and spacing. The advent of automated positioning systems in form of *Global Positioning Systems* (GPS) or *total station survey instruments* (TST) permits the rapid high-precision location of *anomalies* (high and low readings) recorded by geophysical instruments. The output of these surveys is essentially a map of these subsurface anomalies in two dimensions, although georadar adds the third dimension by presenting the anomalies in "depth slices" (see below).

Magnetic Methods

Magnetic archaeological survey, also known as magnetometry, is based on the passive measurement of the earth's magnetic field using highly sensitive magnetometer instruments (Aspinall et al. 2008; Becker 2009; Fig. 1). Magnetic archaeological prospection can be used for the detection of ferromagnetic objects, such as iron objects or slag from metal production sites, causing a relatively strong localized disturbance in the earth magnetic field, as well as for the detection of thermoremanently magnetized, burned archaeological structures, as, for example, hearths, kilns, bricks, or ceramics. The topsoil displays in general a substantially increased magnetization compared to deeper soil horizons and the underlying geological layers, a fact known as the *Le Borgne effect*, which is thought to be based on natural (e.g., forest fires, lightning strikes, oxidation of magnetite to maghemite) and anthropogenic influences (use of fire in prehistoric times). Hence, under favorable geological conditions, it can be possible to successfully locate and map archaeological trenches, pits, and postholes containing prehistoric topsoil in a matrix of relatively lower magnetization (Fig. 2). In order to be able to detect the small magnetic field variations caused by archaeological structures in the presence of a strong earth magnetic field, two magnetometer sensors are placed vertically above each other, resulting in an instrument known as a gradiometer: both sensors measure the effect of the earth's magnetic field as well as any of its temporal variations, which can be caused, for example, by solar activity, while the sensor that is closer to the ground measures the stronger effect of any structures buried within the shallow subsurface. State-of-the-art archaeological magnetic survey is conducted using one or more magnetometers (*fluxgate*/*Foerster* type, *Overhauser*, or *optically pumped cesium magnetometers*) along measurement transects with no more than 50-cm parallel spacing and 10-cm inline sample spacing. In general, no definite information about the depth of structures causing variations in the magnetic data can be derived from magnetic prospection.

Geoelectric Methods

Geoelectric survey, also termed resistivity or earth resistance survey, is based on the measurement of the resistance of artificially injected electrical currents into the subsurface (Hesse et al. 1986). The electrical soil resistance (or its reciprocal value, the electrical conductivity) is strongly dependent on the presence and amount of soil humidity, pore space, and salt and ion content in the shallow subsurface, as well as archaeological features present, which can cause measureable electrical effects at the surface. Positive features, such as stone walls, contrast with negative features, where the soil filling usually retains a greater amount of moisture. In suitable ground and weather conditions, resistance measurements can be used to locate stone structures, walls, and cavities due to their relatively increased electrical resistance, while filled ditches and pits can show by virtue of their relatively increased electrical conductivity. Geoelectric measurements are generally conducted by injecting an alternating electrical current into the soil using two electrodes. The electrical potential associated with the injected current is affected by an electrically heterogeneous subsurface, which can cause a measureable variation of the electrical potential at the ground surface. Therefore, two additional electrodes are employed in commonly used four-electrode arrays in order to measure the electrical potential over a fixed distance. At the surface, soil resistivity represents an average of the values along the flow path of the electrical current and is hence called *apparent resistivity*. The depth of investigation is a function of the distance between the current electrodes. By varying this distance it is possible to investigate the change of apparent soil resistivity with depth. Using a linear multi-electrode array, it is possible to record the soil resistance with increasing electrode spacing at different depth levels, resulting in a so-called *pseudosection*. Most geoelectric archaeological prospection surveys are conducted manually using a fixed electrode frame or fixed

multielectrode arrays with 0.5- or 1.0-m probe spacing, resulting in relatively limited spatial measurement progress. In the UK and in France, experiments have been conducted employing towed carts equipped with spiked electrode wheels. In recent years motorized geoelectric cart systems have been developed in France, permitting considerable spatial coverage rates with three simultaneously measured depths of investigation (Fig. 3).

Electromagnetic (EM) Methods

Electromagnetic (EM) archaeological survey methods comprise magnetic susceptibility, the Slingram method, induction methods, and metal-detecting and ground-penetrating radar (GPR), also known as soil radar or georadar.

Magnetic susceptibility is a dimensionless measure indicating a material's degree of magnetization in response to an applied magnetic field (*magnetizability*). On the earth all materials are naturally exposed to the earth's magnetic field. Using dedicated instruments, sometimes called *Kappameter*, the magnetic susceptibility of soil layers, stones, and objects of archaeological interest can be determined in the field, or soil samples can be taken into the laboratory for measurement. An increased magnetic susceptibility of soil samples can indicate cultural layers due to thermoremanently increased magnetization. Spatial measurements of the distribution of the soil magnetic susceptibility can thus reveal areas of archaeological activity.

The *Slingram* method utilizes a transmitter and a receiver coil with constant spacing between them. A primary low-frequency EM field generated by the transmitter coil is projected into the ground where it induces eddy currents in electrically conducting objects and materials. These induced currents give rise to a secondary EM field that can be detected by the receiver coil, simultaneously measuring the apparent resistivity and magnetic susceptibility of the ground. The method is used widely for the characterization of soils (*pedology*) and in precision farming. Other EM *induction meters* can be used to locate and map changes in clay content and soil humidity, filled-in trenches, walls, as well as areas of increased magnetic susceptibility, indicating cultural layers, fire places. A typical EM induction meter consists of a rod with transmitting and receiver coils mounted at its opposite ends. The system is carried or towed on a sledge horizontally over the ground along measurement transects. Measurements are usually recorded with an inline spacing of several decimeters, while transect spacing in case of instruments with 1-m coil separation should be around 50 cm. The depth of investigation corresponds to approximately half the

transmitter-receiver spacing. Data positioning can be implemented using a global positioning system antenna or reflectors and a robotic TST. State-of-the-art EM induction meters using several receiver coils permit the simultaneous recording of electrical conductivity and magnetic susceptibility of the soil at four depth levels. Using motorized vehicles these systems can cover several hectares per day with 80-cm transect spacing (Fig. 4). A great advantage of the EM method over geoelectric survey (or georadar) is the fact that it does not require a contact to the ground and that it can be used efficiently in environments with high soil conductivity (e.g., wet soils, clay, salt-water beaches, arid regions with high electrical topsoil conductivity).

Metal detectors are manually operated EM induction devices designed for the detection of metal objects in the topsoil and shallow subsurface. In the case of the popular very-low-frequency (VLF) or induction balance detectors, the effect of the oscillating primary EM field generated by the transmitter coil onto the receiver coil is electrically balanced in the absence of a nearby metal object. In the presence of a metal object, this balance is disturbed and the machine emits a visual and audio signal. Modern computerized metal detectors permit the discrimination of metals and the cancelation of effects caused by soil mineralization. The depth of investigation of a metal detector for metal objects the size of a coin corresponds approximately to the diameter of the search coil used. In many countries the use of metal detectors is regulated by law.

Ground-penetrating radar is an active survey method based on the reflection of a short electromagnetic impulse off subsurface layer interfaces and structures with differing dielectric properties, such as buried foundations, cavities, and stones in the shallow subsurface (Conyers 2004). A short electromagnetic impulse with a frequency band between 100 megahertz (MHz) and 1 GHz is emitted into the ground from a transmitter antenna located on the ground surface, and the reflected radar signal is recorded by a receiver antenna as function of the time that has passed since pulse emission. Transmitter and receiver antennae are placed next to each other in commonly used soil radar systems. Depending on the pulse frequency, the power of the antenna output and the electrical conductivity of the soil, signal penetration depths between 0.5 and 5 m depth can be achieved. Georadar measurements are conducted along straight transects and measurements are made with close inline spacing of, for example, 2 or 5 cm. State-of-the-art in professional archaeological survey is a transect spacing of not more than 25 cm when measuring with a 500-MHz GPR

Nondestructive Subsurface Mapping in Field Archaeology, Fig. 6 Georadar depth slice measured with the 16-channel 400-MHz MALÅ Imaging Radar Array (MIRA) with 8-cm transect spacing showing the southern part of the main building at the Forum of the Roman town of Carnuntum. In the high-definition data for the first time the individual brick columns of the hypocaust system under the floor of the easternmost room became visible. (Image courtesy of Archeo Prospections®)

antenna. Exact data positioning is achieved with help of a distance wheel mounted on the GPR cart or sledge and guidance lines placed on the ground with constant intervals, or through the use of a differential GPS with centimeter accuracy. Modern multichannel georadar array systems (Fig. 5) offer dense high-resolution measurements with as little as 8-cm transect spacing (Fig. 6). Densely

measured 2D georadar sections, which can be thought as vertical scans through the subsurface, can be merged into virtual 3D data volumes. Subsequently these data volumes can be cut into horizontal slices, showing structures at approximately the same depth (*GPR depth slices*). Archaeological structures contained in georadar data are often more recognizable when presented in plan view as horizontal depth-slice images. Of all archaeological subsurface methods, GPR generates the largest amount of data and offers highest spatial measurement resolution, horizontally and vertically, and the best chance of assessing the depth of features.

Seismic Methods

Geophysical seismic reflection and refraction methods are only rarely used for archaeological onshore prospection due to the rather time-consuming data acquisition and data processing involved, as well as due to the relatively low imaging resolution. Special application cases are, for instance, the seismic investigation of the depth to bedrock at an archaeological site, or the nondestructive testing (NDT) of architecture using ultrasound. In marine and underwater archaeology seismic geophysical prospection methods, such as *sonar* (e.g., chirp sonar, side-scan sonar), boomer, pinger, sparker, and *sub-bottom profiler*, are successfully used for the detection and mapping of archaeological and historical structures (e.g., wrecks, harbor constructions) on and below the seafloor.

Geochemical Methods

Geochemical archaeological survey methods are based on the mapping of distribution and amount of specific chemical elements and compounds within the soil for localization and delimitation of archaeological sites, as well as for a more detailed analysis of known sites and the function of subareas (Oonk et al. 2009). Compared to the number of geophysical surveys, the number of reported geochemical surveys is small, due to the relatively slow data acquisition involved. Most commonly employed have been soil phosphate measurements using sample intervals between 1 and 50 m with the goal of locating and delimiting prehistoric settlement sites. Increased phosphate values can indicate the presence of cultural layers of archaeological interest due to the release of phosphate ions during the decay of deposited organic material (occupational waste and manure) and their subsequent binding to soil particles. Other geochemical prospection methods involve the analysis of heavy metals in archaeological soils to identify metalworking sites. Aside from increased phosphate, archaeological soils commonly show anomalous levels of calcium, copper, magnesium, potassium, sodium, and zinc. One concern regarding geochemical mapping for archaeological prospection is the comparability of data values obtained from different soil phases. Geochemical methods are also erosive since samples have to be taken.

Future Directions

Archaeological subsurface surveys all map variations in the physical or chemical properties of the topsoil and the near subsurface. Digital systems generate the maps as gray scale (Figs. 2 and 6) or color-coded raster images located on the local or national grid. The use of Geographical Information Systems (GIS) aids interpretation by presenting these geophysical maps within the context of previous discoveries or modern land use (Neubauer 2004). Improved digital imaging is an important part of current R&D.

The most important parameters affecting the efficiency of subsurface archaeological prospection methods are sensitivity, speed, and sample spacing (Becker 2009). Considerable advances have been made using motorized multichannel systems with GPS positioning and navigation. Understanding of the nature of structures observed in geophysical data is being improved empirically by comparison with the results of subsequent excavations. Research into the visibility of buried archaeological structures using different survey methods continues. Of particular interest in this regard are "ghost" structures visible in the geophysical record that fail to show during subsequent excavation.

Non-places in Archaeology

Carolyn Nakamura
Leiden University, Leiden, The Netherlands

Introduction

The question of "non-places" in archaeological research is likely to evoke strange reactions from archaeologists and non-archaeologists alike. In both a practical and discursive sense, archaeology is in the very business of *making places* as it substantively engages in processes of materializing and articulating the absent, the forgotten, the concealed, or even the excessive (Buchli et al. 2001: 171). Namely, archaeology articulates these undisclosed figures and processes as distinctive places, what we have come to understand as archaeological sites and "the past."

How, then, are we to understand the archaeology of non-places? The term "non-place" used by archaeologists comes from the French anthropologist, Marc Augé, who views non-places (*non-lieux*) as an opposite polarity to "anthropological places," which are generally regarded as localized, organic, familiar, known, occupied, and meaningful to both occupants and observers (Merriman 2004). Places come into being through the ongoing negotiation of social relations, shared histories, and identities (Augé 1995). While non-places take part in this negotiation, they represent the negative polarities of such processes. Moreover, for Augé, non-places and their proliferation are a distinctive characteristic of supermodernity and include spaces of transit or faceless transaction that tend to evoke feelings of isolation, detachment, and suspension. In short, non-places appear to lack a sociality characterized by a sense of rootedness, attachment, and belonging.

Evocative of transience, suspension, and unrootedness, non-places orient the archaeological gaze towards the abject, the subaltern, and the marginalized. These subjects are often viewed as the embarrassing underside of history and society, as they remind us of humanity's failings, malice, and brutality; they also evoke feelings of alienation, isolation, and willful forgetting. Histories of the abject and dispossessed often dissolve into non-places – the scars or ruins of modernity (or history) – because they inspire little if any personal or collective investment in them (Moran 2004). But the material record does maintain traces of such histories and archaeology stands to offer a unique perspective into those histories of human society and culture largely neglected by or inaccessible to discursive productions of scholarly analysis.

The archaeology of non-place, then, marks a critical turn to actively incorporate histories of the subaltern and dispossessed into the field of archaeological knowledge. While the concept of "non-place" has particular resonance with those who study the archaeology of the contemporary past or present (Gonzalez-Ruibal 2008; Harrison and Schofield 2010; Harrison 2011), its application need not be limited to examinations of the twentieth and twenty-first centuries. Processes of exclusion and marginalization as well as experiences of alienation and isolation are not restricted

to the (post/super) modern experience. They are a part of almost every "complex" society. We might therefore refigure the concept of non-place in terms of the more general idea of an archaeology of alienation articulated through material, social, spatial, and temporal vectors. This specific attention to subaltern histories provides a fuller archaeological accounts of the past and gives the discipline some political teeth in its accounts of the historical past and the present.

Key Issues/Current Debates

Augé's Non-lieu

We should begin by revisiting Augé's specific idea of non-place and why it has gained some traction in archaeological circles. While the term "non-place" has appeared in many, it is a concept that has received much critical attention and has received much criticism, much of which is valid and some of which likely derives from miscues from the peculiar style of this particular ethnographic project. Merriman notes that *Non-Lieux, Introduction à une anthropologie de la surmodernité* (1992) should be taken as a form of self-analysis through a fictional style of ethnological writing (2004: 149). With this project, Augé does not seek to present multitude of potential experiences. With reductive simplicity, Augé states: "If a place can be defined as relational, historical and concerned with identity, a space which cannot be defined as relational, or historical, or concerned with identity will be a non--place" (Augé 1995: 78). His analysis focuses on spaces of transit – airport lounges, motorways, theme parks, supermarkets, and motels – that he sees as coming into experience and memory only partially formed. These are non-places, material, physical, and inherently transitional.

Contrary to Augé's Pierre Dupont in fluid movement, there are many who would not experience these spaces as non-relational, non-historical, or sites of non-identity. There are also places where people get stuck, sometimes to the extent that they become suspended in (and in some ways defined by) their denied access to history, social relations, and identity. Augé's style of semi-fictional, ethnological self-analysis asserts one perspective over numerous other possibilities, including those that would foster a more habitual, long-standing engagement with these spaces. Given this limited vision, Augé's conceptualization of the non-place has been criticized as being conceptually blunt and lacking the nuance necessary to address the heterogeneous complexity of sociomaterial forms, relations, and networks (see Merriman 2004: 147–52; Latour 1993: 100–1). Despite this limitation, Augé, in the end, does retreat from a blunt opposition between place and non-place. Rather, he underscores the co-constitutive play that defines the relationship between the two: "[non-place] never exists in its pure form; places reconstitute themselves in it; relations are restored and resumed in it . . . Place and non-place are rather like opposed polarities: the first is never completely erased, the second is never totally completed; they are like palimsests on which the scrambled game of identity and relations is ceaselessly rewritten" (Augé 1995: 78–9).

The often quoted definition of non-places as "non-relational, non-historical and not about identity" is therefore misleading. Non-places are not relationally and socially bereft; rather, they provoke and enable modes and socialities of dwelling-in-movement or dwelling-in-betweenness as a counterpoint to dwelling-in-place (see also Sekedat and Aldred 2011). As Augé states, "a person entering a space of non-place is relieved of his usual determinants. He becomes no more than what he does or experiences in the role of traveller, customer or driver" (1995: 103). But this description of non-place assumes that the "social game" is always being played elsewhere, namely, in a place (Augé 1995: 111). However, the "gentle form of possession" one might experience in non-places – what Augé describes as identity-loss – is not always temporary or gentle. Those non-places that delineate the margins rather than the articulating nodes of society – slums, refugee camps, tent towns, clandestine detention centers – can suspend their dwellers in a long-term or even semipermanent state of transience and negation. For pavement dwellers, slum residents, refugees, and numerous others, dispossession becomes a significant part of their identity and relations.

In a sense, non-places produce non-persons – those stripped of the basic social "determinants" that allow their full recognition by the state and other members of society. In some cases this stripped state is not merely temporary. Abject non-places differ from locations such as airports, transit systems, and shopping malls in the sense that their "visitors" do not engage in contractual relations with such spaces or the powers that govern them (see Augé 1995: 101). There is no check-out counter, toll booth, or passport control from which one can "retrieve" and assert his or her identity, reclaiming the rights and recognition it entails. The camp, slum, or detention center is often marked by the lack of contractual relations. Here, the contract is null and void. Transience, suspension, and nonrecognition become a way of dwelling (in relation to the governing powers and normative practices), and the non-place takes on place-like qualities, where "travelers" are forced to grow roots, as it were. Non-places at the social, economic, and political margins critically demonstrate how the interplay of place and non-place articulate complex, heterogeneous, and dynamic constitutions of social spaces and agents.

Examples

Contemporary spaces of the abject and the dispossessed perhaps have most captivated the archaeological gaze focused on the present day. Not trivially, it is in the examination and constitution of material traces of the abject, alienated, and subaltern that marks a critical archaeological contribution to contemporary culture studies (Buchli et al. 2001; Buchli 2007; Harrison and Schofield 2010). Archaeological expertise is not just about locating and illuminating a distant and remote past. Rather, on a more general level, it is about uncovering that which has remained unspoken, hidden, or overlooked. Unlike other disciplinary forays into contemporary material culture studies that tend to aim at discursive forms, archaeology, by necessity, has become adept at negotiating the non-discursive, quotidian traces human activity. This focus is critical: through the archaeological attention to non-discursive, taken-for-granted activities, "the archaeological act comes directly into contact with the subaltern, the dispossessed and the abject" (Buchli et al. 2001: 14). Buchli and Lucas critically remind us that the realm of discourse (and the realm of most scholarly work) is the realm of the enfranchised, whereas the non-discursive realm of the quotidian and taken-for-granted often leaves the only traces of subaltern activities and experiences (Buchli et al. 2001: 14). In the study of the contemporary past, archaeology can uniquely examine and help constitute the histories of those people whom society pushes to the margins. Indeed, many scholars argue that given this distinctive position, archaeology has a particular obligation to bring to light those obscured and often painful pasts that haunt contemporary life, and a responsibility to the individuals, communities and institutions implicated by archaeological work to help them come to terms with their recent hidden histories and ongoing circumstances (Buchli 2007; Harrison and Schofield 2010: 9; Zimmerman et al. 2010).

An emergent archaeological subfield now focuses on spaces of the abject or the "scars" of modernity (Gonzalez-Ruibal 2008), such as mass graves and genocide (Crossland 2000, 2002; Funari and Zarankin 2006; Ferrandiz 2006; Gonzalez-Ruibal 2008); landscapes of war and conflict (Schofield 2005, 2009; Saunders 2007); concentration camps (Kola 2001; Myers 2010; Myers and Moshenska 2011); the homeless (Zimmerman and Welch 2006), the welfare state (Harrison 2009), abandoned buildings, parks, and towns (Edensor 2005; Pringle 2009; Andreassen et al. 2010), and places devastated by disasters (Gould 2007). These are non-places of the recent past and present, but both have a distinct orientation towards articulating a particular history of the modern condition. Many of these engage with and extend studies of the "contemporary past" (Rathje 1979; Gould and Schiffer 1981; Buchli 1999; Graves-Brown 2000; Buchli et al. 2001; Rathje and Murphy 2001) and combine conventional archaeological methods and analyses with those

from ethnography and textual, material, and visual culture studies. Oftentimes, there are explicit political projects underwriting the study of modernity's detritus and failures, whether it is putting archaeology to work as bearing witness to an abject, forgotten past, or as a kind of therapeutic project in reconciliation and retribution or as a political commentary on the conditions and issues of the present (Harrison and Schofield 2010: 149). In this arena, archaeology gains political teeth and social relevance and, in many instances, aligns itself with social justice and heritage ethics.

The challenge of non-places also brings attention to the noninvasive methodologies of archaeological analysis and how they can be uniquely employed in the study of the present. Archaeological non-places are not just abandoned ruins and uninhabited sites hiding in plain sight (Harrison and Schofield 2010). They are, of course, also inhabited. Indeed some archaeological methods combined with new technologies can be used to examine physically inaccessible sites. Adrian Myers has used Google Earth to track the growth of Camp Delta at Guantanamo Bay, demonstrating how traditional archaeological analyses combined with satellite imagery can quantify the material manifestations of secretive government policies (2010). When applied towards challenging official governments statements, the use of such viewing technology can serve to democratize the "panoptic gaze" traditionally reserved for the powerful (Bernbeck 2008); importantly however, Myers reminds us that it also produces an essentially distancing and potentially dehumanizing perspective and thus should be used ethnically, ideally in concert with other more intimate, on-the-ground archaeological techniques (Bernbeck 2008). On the flip side, archaeologists are also employing standard archaeological methods such as survey, mapping, photography, and artifact collection to study transiently inhabited sites such as Black Rock City at Burning Man (Carolyn L. White) and the sites and material culture of undocumented migrants crossing the southwest American border (Jason P. de Leon).

Future Directions

From Augé to the archaeologists that have mobilized his concept, the non-place appears as a distinctly modern or contemporary feature of society. However, I would argue that a theory and politics of non-place could have a much broader application in archaeology. What is common in all accounts and applications of the non-place are notions of alienation and suspended recognition that take on spatial and material entailments. Non-places, past and present, direct our attention to those histories that often lie outside the lines of traditional archaeological inquiry – the more visible hegemonic and normative practices and structures. And yet, as Victor Buchli, Gavin Lucas, and others have persuasively argued, archaeology is uniquely equipped to deal with the unarticulated histories of the dispossessed and subaltern. Furthermore, such histories provide important and evocative counterpoints to dominant historical modes and narratives we have so far produced and stand to provide a richer and more balanced picture of the human condition in various times at various places.

Archaeology has made some notable strides in this general direction. For decades, many researchers have increasingly pursued archaeologies "from below." Many projects now form research questions around and implement methodologies to analyze quotidian activities and practices, and there is an expanded focus on "non-elite" and non-monumental structures and sites. But these projects still maintain a distinct focus on normative, dominant structures rather than on the subaltern and alienated. The question then is how might one locate a non-place (which may or may not have been materially enduring) in the archaeological record, especially in the absence of written records and archives that may have marked its existence? If we are speaking of locating sites such as ancient detention areas, or refugee camps, then it is often a matter of luck (for example, the fortuitous finding at Vindolanda during the 2011 excavations). But merely locating such "non-places" is not tantamount to an archaeology of non-place. Rather, it is a particular kind of

(postcolonial) attention to the analysis of human activity that constitutes such a project.

Attending to the pasts and histories of those at the social margins, embraces a certain kind of postcolonial logic and also stands to provide a more resonant and fuller account of the past. While articulating the histories of the subaltern and abject in ancient times may lack the political urgency of similar projects focused on the present (there is no chance of generating strategies for political change), these histories nonetheless may testify to the lives and conditions of persons from diverse sectors of society but also complicate and challenge our current understandings of ancient hegemonic forms. Just as detention centers, homeless camps and abandoned theme parks reveal the abuses, inequalities, and failures of modern societies and thus contribute to a more balanced view of modernity; the study of past non-places may similarly provide more nuanced accounts of ancient life and societies.

An archaeology of non-place thus requires a shift in perspective and mode of intellectual inquiry. Following Ian Lilley, subaltern and marginal histories should not only be articulated and investigated; rather, it is also a matter of "moving the interests of the periphery to the center" (2011: 142). This shift should not only apply to contexts of the recent or contemporary past. Rather it should inform the archaeological project more broadly. The greater value of doing an archaeology of non-place lies in the way it stands to fill in some discursive "blind spots" of traditional archaeological knowledge. What interpretive possibilities emerge when we focus our analytical gaze first on the place of transit, the slum, the ludic object, or daily practices of the dispossessed? Situating the spatio-material entailments of alienation at the center of archaeological inquiry does the double work of compelling researchers to ask why certain places, objects, and narratives have been written out of history while at the same time asserting their right to be "recorded" in the archaeological record.

Within archaeology, Augé's concept of non-lieu connects sites of transition, movement, and in-betweenness to states of alienation, abjection, and dispossession. Given the unique expertise of archaeology in dealing with non-discursive material traces and remains, the discipline has a certain obligation to further pursue and develop its interpretive sensibilities to include those pasts and histories which have been historically excluded.

N

Nonstructural Sites: Monitoring

Milford Fletcher
National Park Service, Ret, Tijeras, NM, USA

Introduction

After the initial inventory of an archaeological site, periodic visits may be required to determine that the site conditions have not been altered by either naturally occurring events or by human intervention. Although the methodology of inventory is often outlined in considerable detail, the

techniques of monitoring sites are much less rigorously defined.

Definition

Nonstructural archaeological sites include a vast array of cultural remains which are not buildings or structures. Rock art sites, battlefields, mounds, flint quarries, and painted caves are common examples of nonstructural archaeological resources. Many of these sites are located below the ground surface, and their significance is unknown until appropriate analysis can be conducted.

Key Issues/Current Debates/Future Directions/Examples

The laws, policies, and regulations that are the basis of historic preservation are usually outlined in considerable detail by the national, state, or tribal entities which manage them. A considerable body of information, guidelines, and procedures is available in the professional literature (National Park Service 1983; Hardesty and Little 2000; King 2000). The legal frameworks that constitute tribal, state, and national preservation programs clearly specify requirements for the identification of sites for eligibility to various lists. Inclusion on these lists elevate the sites to national or international status for the recognition of outstanding cultural value to society. Two examples of such programs are the National Register of Historic Places in the United States (NRHP) (National Park Service 2002) and the World Heritage list maintained by the United Nations Educational, Scientific and Cultural Organization (UNESCO World Heritage List n.d.).

Because of the wide variety of nonstructural sites, environmental conditions, and possible impacts, a single set of monitoring criteria is not feasible. Those who seek guidance in formulating monitoring practices will find considerable information on the inventory techniques but little information on monitoring. In many cases, monitoring is perceived as a one-time effort in conjunction with construction or earth moving to identify cultural resources. Literally thousands of nonstructural sites have been identified in preparation for highway construction, damming of waterways, encroachment of suburbs, etc., but the results have been primarily "salvage archaeology" and not monitoring in the strict sense. Land modification by grading and earth movement is particularly damaging to small surface sites. Many members of the public may not be aware of the historic preservation laws and not fully understand the damages their own actions may do.

In other cases, monitoring consists of posing security personnel at the sites, primarily to curtail looting and vandalism (UNESCO n.d.).

The reason for this is that a far greater number of sites are seriously damaged or destroyed by human actions than by natural processes (Wood and Johnson 1978; Wildesen 1982).

The need for systematic monitoring is frequently mentioned in requirements to protect historic/archaeological properties, but is not discussed in detail. Given limited funding, many programs focus their monitoring efforts on a very narrow range of highly sensitive and/or highly visible sites, such as rockshelters, rock art, mounds, cemeteries, and battlefields that are primarily threatened by looting and vandalism. Such efforts may (depending on field protocols and data management) be adequate for those sites, but such highly selective monitoring is not really sufficient for compliance with the intent of relevant historic preservation law. Extended site monitoring is thus often seen as an activity that is important but less critical than site discovery and evaluation.

One innovative monitoring program in the western United States seems to be working well. This program, called SITEWATCH, is currently being used by several US government entities including the National Park Service, the US Forest Service, and the Bureau of Land Management (New Mexico Historic Division 2007). Sitewatch recruits and trains volunteers from the public sector who then are assigned particular sites to monitor. Participants provide their own transportation, cameras, and other equipment and try to visit the

site on a regular basis. After each visit, a short form and relevant photography are submitted to the managing agency. This program shifts some of the financial and labor costs from the managing agency to the volunteers.

The US military manages thousands of hectares of land containing cultural resources. The US Corps of Engineers has developed criteria and protocols which address how to best monitor archaeological resources (Department of the Army US Army Corps of Engineers 2009). The focus of their guidelines is to detect changes and mitigate damage. Also addressed is perhaps the most difficult part of monitoring which is data management. The rapid technological changes in global positioning units, digital cameras, high-resolution photography, and custom software can make compatibility across time and computer platforms difficult.

A particularly sensitive environment is that of caves in which drawing or paintings are located. One cave in particular which has received considerable recent attention is that of Lascaux in France. Discovered in 1940, it was opened to the public in 1948 and up to 100,000 visitors per year entered the cave to view the magnificent paleolithic paintings. Over the years, several species of fungi, algae, and mold have been transferred from visitors or equipment to the atmosphere of the cave and consequently to the cave walls and paintings. In addition, lint and other organic materials are shed by visitors as they move through the cave environment. Lint, dead skin cells, and other organic materials act as a food source for microorganisms (Jablonsky et al. 1993).

By 1963 changes of airflow, relative humidity, and aggressive growth of microorganisms ultimately lead to the closure of the cave to general visitation, and a replica of a portion of the cave was created nearby. The lessons learned from this have lead to the closure of a number of painted caves to the general public. Some cave environments are so delicate that general visitation by the public will never be feasible without significant detriment to the resource (Bradshaw Foundation n.d.). Conversely, caves such as the World Heritage Site of Sterkfontein which are devoid of significant rock art are routinely visited without damage to the resources which, in this case, are remains of ancient hominids (UNESCO Cradle of Humanity n.d.).

A successful monitoring program requires a significant commitment of both time and money. Many monitoring programs are managed by tribal, state, or national entities where personnel and budget constraints may curtail or even eliminate a monitoring program. A successful monitoring program will identify goals, possible impacts, and treatments, develop appropriate forms for recording conditions, and identify standard operating procedures. Baseline and routine monitoring procedures will be established and documented. There must be written protocols for the use of electronic equipment (digital cameras and global positioning units) to assure the uniform and consistent acquisition and management of data.

The proliferation of devices such as smartphones and electronic tablets makes monitoring information easier to acquire, and these data can often be imported directly into existing programs and files. Regardless of how the data are acquired, they should be backed up on a routine basis and a copy of all data should be stored off-site. One new feature of the Internet is the concept of the "cloud" which allows data to be stored on an external server on the Internet. Authorized personnel can then retrieve and edit these data. Since the software used to manage data will probably be revised and updated over time, the data must also be kept up-to-date. Standard off-the-shelf software programs should be used to insure a smooth transition in the event key personnel are moved or new computer systems are acquired.

Norms of Quito (1967)

Alfredo Conti
National University of La Plata and ICOMOS, Ensenada, Argentina

Introduction

The document known as Norms of Quito is the outcome of an experts meeting convened by the Organization of American States (OAS) between 29 November and 2 December 1967, held in the capital city of Ecuador, to discuss on the preservation and utilization of monuments and sites of artistic and historic values of the Americas, especially those located in Latin America. Since the document can be considered a milestone in the evolution of the theory and practice of heritage conservation, the central purpose of these notes is to highlight the main aspects introduced and developed in the Norms of Quito. In order to better understand its significance, it is necessary to shortly explain the context in which it was conceived, both in terms of the situation in the Americas and in the field of monument conservation and restoration.

Definition and Key Issues

The Organization of American States was created in 1948; among other purposes, it seeks to promote social and economic development, fostering dialogue and strong relationship among the countries of the Americas. In 1961 the USA launched

the program Alliance for Progress with the aim of canalizing the economic and social assistance of the country to Latin America. One of the main meetings promoted by OAS over that period was held in Punta del Este, Uruguay, in April 1967. The final document stresses the compromise of reinforcing the objectives of the Alliance for Progress and, among other issues, the economic integration and industrial development of Latin America, the multinational action for infrastructure projects, and the educational, scientific, and technological development. Among the aims of education, it is explicitly cited to create or reinforce the services of conservation of the cultural heritage. In this framework, it is possible to state that the Norms of Quito are a typical product of the period; the idea of economic and social development was crucial at that time; the document places cultural heritage as a resource to reach that goal.

Up to the 1960s, just a few international meetings on conservation of monuments and sites had been held. The first international document on heritage conservation is the Athens Charter of 1931; in 1964, a second International Congress of Architects and Technicians of Historic Monuments was held in Venice. The outcome of that meeting is the International Charter for the Conservation and Restoration of Monuments and Sites, known as the Venice Charter, which sets out doctrinaire and theoretical principles that guided technical interventions over the last 50 years. Another result of the Venice meeting was the foundation, 1 year later, of the International Council on Monuments and Sites (ICOMOS), the main worldwide non-governmental organization which deals with heritage protection and conservation.

The Venice Charter, one of the milestones in the evolution of the theory of conservation and restoration, is a short text elaborated by experts and addressed especially to experts. The document of Quito completes the ethical contents of the Venice Charter with operational principles oriented to the utilization and enhancement of monuments and sites of historic, archaeological, and artistic values. Maybe the most important conceptual idea is that monuments and sites constitute economic resources in the same sense as the natural wealth of the country, and they can become therefore instruments for development and progress. The document introduces a series of concepts that anticipate the idea of "integrated conservation" that would appear in the 1970s: not only technical aspects are considered but also economic, social, juridical, and administrative. The necessity of integrating conservation of monuments and sites in the framework of national territorial planning and the active participation of communities are stressed. In this sense, it is a document addressed to a wider audience than the Venice Charter and, especially, to decision-makers related to public policies, planning, and economic development.

The idea of utilization of monuments and sites had been cited in the Venice Charter when setting out that "the conservation of monuments is always facilitated by making use of them for some socially useful purpose." The Norms of Quito further explores this aspect and makes usability of cultural heritage as one of the main topics of reflection. Monuments and sites must fulfill a social function. The idea of "enhancing" is introduced in the sense of making maximum use of existing resources; the proposal is incorporating economic potential, "making an exploited resource productive," by a process that enhances its historic or artistic significance and "raises it from exclusive domain of erudite minorities to the awareness and enjoyment of the masses."

One of the main sections of the document is dedicated to monuments and sites as tourist attractions. Even if there were some previous documents that dealt with the relationship between cultural heritage and tourism, the Norms of Quito anticipate one of the main issues that arouse in the field of heritage conservation and management over the end of the twentieth and the beginning of the twenty-first centuries, when tourism appears as an extraordinary economical force that has both positive and negative impacts on cultural assets. The document of Quito establishes that tourism can contribute to raise awareness on the importance and national significance of monuments; together with adequate restoration and

maintenance, infrastructure works are also required to complete the travel plant of a region.

Current Debates

Forty-five years after the meeting of Quito, the situation of the countries of the Americas, the evolution of theory and practice of heritage conservation and management, and the very concept of cultural heritage have considerably changed. It does not mean, nevertheless, that the Norms of Quito should be considered only a historic document, a step in the evolution. Some of the issues introduced in 1967 are still a matter of reflection and debate; some of the situations regarding the lack of adequate protection or management of cultural heritage can still be observed, not only in Latin America but also in other regions of the world. The relationship between cultural heritage and sustainable development is at the center of the current debate and was proposed by UNESCO for the commemoration of the 40th anniversary of the World Heritage Convention in 2012. When reading the Norms of Quito today, it becomes evident that, although the document was conceived taking into account especially the situation of the Latin American countries, the approach and principles can be applied to different geo-cultural contexts and most of them are still valid. It is a document that can be revisited because it is still a source of inspiration for reflection on how to adequately manage cultural heritage.

Introduction

North Africa was a remarkably prosperous territory throughout its ancient history and under Roman rule achieved a level of affluence to which the physical remains attest. It was the birthplace of the Severan dynasty (late second to third centuries CE) and the home of such literati as Terence, Apuleius, Tertullian, and St. Augustine. It made significant contributions to the agricultural wealth of the Roman Empire and had thriving ceramic and mosaic industries. By the second century CE, the region counted over 600 cities, many of which contained striking examples of monumental architecture.

The French were the first to excavate the region following their invasion of Morocco, Algeria, and Tunisia in the nineteenth century; they dominated all fields of North African study well into the twentieth century. The Italians have imparted a similar colonial legacy in Libya, where they continue to be the primary excavators. Only after the Second World War did other international groups become involved, in particular the British, Canadians, Americans, and, since the 1970s, Maghrebian scholars.

There were two broad ethnic groups by the time of Roman occupation: those whom the Greek sources called Libyans (and whose descendants modern historians call Berbers) and the Carthaginians, or western Phoenicians, whom the Romans called *Poenici*. The Libyans were the earlier inhabitants: though their precise origin

is uncertain, it seems that they migrated westward from the Egyptian Sahara and occupied much of the region by at least the second millennium BCE. Centuries later, the Libyans were widely dispersed and had developed into a number of different peoples with their own regional traditions and dialects. Chief among them were the *Mauri* of Morocco and western Algeria, the *Numidae* of the Tell in northwestern Tunisia and northeastern Algeria, the *Gaetuli* of the coastal hinterland between the Atlantic coast and the Gulf of Syrtes, and the *Garamantes* of the Libyan pre-desert. Ancient sources made reference to a number of other tribes and subtribes based on geographical, ethnic, cultural, political, and linguistic grounds, but these are often vague and conflicting. Nonetheless, it seems that the *Mauri*, *Numidae*, *Gaetuli*, and *Garamantes* were confederations at the top of the tribal hierarchy, made up of conglomerates of various tribes and subtribes (Fig. 1).

Definition

Roman North Africa refers to the northwestern region of the continent that was ruled by the Romans as a series of provinces for over 500 years. Roman occupation began after the destruction of Carthage in 146 BCE and the subsequent annexation of its territory as the province of *Africa Vetus*, in modern Tunisia. At its greatest extent, in the third century CE, it occupied the littoral plain north of the Sahara, between the Atlas Mountains in the west and the Altars of Philainos on the Gulf of Syrtis in the east.

Historical Background

Sometime in the first half of the first millennium BCE, the Phoenicians founded a series of trading colonies along the coast of North Africa, the most important of which was Carthage. Their primary interest in the area, at least initially, was directed toward western Mediterranean trade, rather than the establishment of settlement colonies and the development of African hinterland. The Phoenicians established a number of other trading posts throughout the western Mediterranean, namely, Spain, Sardinia, Sicily, and Malta, to achieve these same ends. It was not until the fifth century BCE, after defeat by the Greeks in Sicily and victory over the Libyans in northeastern Tunisia, that Carthage turned its attention inland, in

North Africa, Roman, Fig. 1 Distribution map of peoples in North Africa (Law 1978a: 142, Fig. 22). (Copyright of Cambridge University Press 1978. Reprinted with the permission of Cambridge University Press)

particular, toward the fertile Cape Bon peninsula. Here, Carthage developed a number of large estates that produced a variety of cash crops; this area increasingly became the chief focus of economic and political interest in the third century BCE as Carthage lost control of the western Mediterranean in the Punic Wars (264–146 BCE) with Rome.

The First Punic War (264–241 BCE) was the first of three wars that witnessed the increasing involvement of Rome in the political, economic, and social affairs of North Africa, which the Roman historians Polybius, Livy, and Diodorus Siculus describe. Interactions between Rome and Carthage during the fifth and fourth centuries BCE were generally limited to a series of treaties detailing trading rights in the western Mediterranean and, in the third century BCE, an alliance to oust King Pyrrhus of Epirus from Sicily. By this time, Rome had consolidated her power over southern Italy and was increasingly concerned over Carthaginian involvement in Sicily. War broke out between them over control of the island, at the end of which the Romans had succeeded in driving out the Carthaginians, while forcing them to pay heavy indemnities.

The loss of Sicily, and subsequently Sardinia, compelled Carthage to seek new sources of capital in Spain. This proved to be a successful strategy, and Carthage, under the leadership of the Barcids, gained considerable wealth and manpower from this new territory. This was a source of alarm for Rome, who established a treaty with Carthage in 220 BCE limiting Carthaginian expansion to the river Ebro in Spain. Rome, moreover, had formed an alliance with a town south of the Ebro, Saguntum, which lay within Carthaginian limits. When Hannibal besieged the town in 218 BCE, the result was a renewed conflict between Rome and Carthage, the Second Punic War (218–201 BCE). Despite a series of early victories, the Carthaginians were defeated by a Roman invasion of North Africa. Carthage had now lost Spain and a number of African territories, was forbidden to wage war without the permission of Rome, compelled to assist with Roman wars, and forced to pay an annual indemnity.

The terms of peace between Rome and Carthage also granted to Masinissa (c. 240 or 238 to c. 148 BCE), king of the *Massylii* and Roman ally, the restoration of all lands ever belonging to him or his ancestors. Whether these lands comprised the territory surrounding Carthage or not, Masinissa nonetheless began a gradual encroachment of Carthaginian territory. Carthage was not permitted to declare war according to the terms of the treaty, and Rome elected not to intervene. The subsequent outbreak of war between Carthage and Masinissa in 150 BCE constituted a breach of the treaty, and the following year, Rome declared war on Carthage. This engagement was the Third Punic War (149–146 BCE), which resulted in the destruction of Carthage and the annexation of its territory as the Roman province of Africa.

The nature of Roman involvement in the area for the next two centuries was sporadic and military. In 111 BCE, Rome declared war on Jugurtha, a descendant of Masinissa, when a struggle for the Numidian throne led him to kill a number of Italian settlers. Following his defeat, Rome established a series of client kings, who were variously involved in the civil wars between Marius and Sulla and subsequently Caesar and Pompey. Caesar's victory in 46 BCE brought an end to the civil war and much of the Numidian kingdom. The territory of North Africa at this time was reorganized: the original African province was now called *Africa Vetus* and the new annexation, *Africa Nova*. To the west, Octavian annexed Mauretania in 33 BCE and subsequently reestablished it as a client kingdom; in 29 BCE, he sent a *deductio* of colonists to Carthage and by 27 BCE had united *Africa Vetus* and *Africa Nova* as *Africa Proconsularis*. The late first century BCE to early first century CE witnessed a number of revolts in the pre-desert areas that resulted in the permanent installation of the Third Augustan Legion in southern Numidia and a second annexation of Mauretania in 40 CE.

At this point, North Africa was fully absorbed into the Roman Empire, and its administration changed accordingly. A *proconsul* governed *Africa Proconsularis*, the most important,

wealthy, and urbanized province of the region, as a senatorial province. Its territory included much of Tunisia, eastern Algeria, and the littoral of western Libya (later known as Tripolitania). A legate appointed by the emperor, however, controlled the legion stationed in the Algerian portion of the province nearly independently. *Mauretania* was administered by equestrian *procuratores* as two separate provinces, *Mauretania Caesariensis* in the east and *Mauretania Tingitana* in the west.

There was relatively little military presence in the provinces during the first two centuries CE. The Third Augustan legion, which consisted of approximately 5,000 legionaries and 15,000–20,000 auxiliaries, occupied all 110,000 square miles of the region. Half of these were stationed in *Mauretania Tingitana*, conversely one of the most heavily militarized provinces. The other half were stationed in southern Numidia, along the *limes* (frontier) of *Mauretania Caesariensis* and Tripolitania, first in Ammaedara, then Theveste, and, by the beginning of the second century, Lambaesis. These areas were also the location of a number of veteran colonies, particularly in southeastern Numidia, whose inhabitants remained culturally distinct from the majority of the indigenous population.

Apart from a few cities founded by Romans, the majority were of Punic and Libyan origin. The lowest ranking were the peregrine *civitates*, non-citizen communities that were recognized by Rome as self-governing and thus retained their pre-Roman magistrates, *sufetes*. Leading inhabitants often petitioned for these communities to become *municipia*, which adopted Roman constitutions and whose senior magistrates were granted Roman citizenship. The highest-ranking settlements were the *coloniae*, all of whose freeborn residents obtained Roman citizenship, whether or not any Roman colonists had ever settled there.

Administration of these settlements was typically undertaken by local city magistrates, and in communities that adopted Roman styles of government, the *decuriones* were chiefly responsible. They were involved in the collection of taxes, the handling of local law courts, and the construction and maintenance of public buildings; they also comprised the local city council (*ordo*) in each community. It was under their direction that North African cities developed a characteristically Roman appearance: *fora*, theaters, circuses, baths, temples, and amphitheaters were erected in most cities from the late first to early third centuries CE. The decurial office became increasingly prestigious and lucrative, since it offered lower ranking magistrates and wealthy North Africans the opportunity to achieve the authority, distinction, and recognition with which they were able to rise in the imperial administration.

For Rome, the chief objective of these magistrates and their cities was contribution to the *annona* in the form of taxes paid in-kind. These primarily consisted of agricultural foodstuffs: grain, which by the mid-first century furnished two-thirds of Rome's yearly grain supply, and olive oil, initially from Tripolitania, and in the late-second-century Tunisia as well. To achieve these ends, land was farmed intensively and the pre-desert areas heavily irrigated. Much of this land consisted of imperial estates leased out to private individuals, typically senators, under long-term leases. Free peasants farmed the land as sharecroppers on behalf of their landlords, and in the second century CE, the imperial government offered incentives that promoted not only increased production but also stability in tenure.

North Africa continued to prosper under these conditions well into the early third century CE. Cities grew in size and number: by this time there were 500–600 cities, 200 of which were located in the fertile areas of northern Tunisia. Agricultural production of grain and olive oil spread into the pre-desert areas to satisfy demand; on a smaller scale, the ceramic, textile, and quarrying industries increased. A number of the local elite, strengthened by their newfound wealth, had entered into the imperial administration. Many became senators and acted as patrons of their native cities, petitioning to raise the status from *municipium* to *colonia*. These kinds of developments accelerated during the reign of Lucius Septimius Severus (193–211 CE), the founder of the Severan dynasty of Roman emperors and a native of Lepcis Magna. Under his rule many

North African communities were given municipal rights; to his hometown he granted the highest possible status for a provincial city, that of *ius Italicum*, which exempted it from certain forms of taxation. The province of *Numidia* was created from the southeastern region of Algeria and populated by the legion and veteran colonies.

A rebellion in 235 CE brought this prosperity to an end. The legions stationed in Pannonia had murdered the last of the Severans and proclaimed their commander, Maximinus Thrax, emperor. As a reward for their loyalty, Maximinus doubled the soldiers' pay and raised taxes in order to cover the costs. These exactions were particularly heavy in *Africa Proconsularis*, and in 238 CE, a group of landowners there murdered the *procurator* and proclaimed their *proconsul* Gordian emperor in revolt. The Numidian-based legion remained loyal to Maximinus, however, and ensuing conflict between the two groups resulted in the death of Gordian, his son, many of their supporters, and a number of the landowning elite. The next 50 years were marked by a succession of soldier emperors whose rule weakened North Africa, particularly at its borders. The dissolution of the Third Augustan Legion in 238 CE left the provinces largely defenseless to a series of attacks by Libyan tribes, which, despite the legion's restitution in 253 CE, resulted in the abandonment of *Mauretania Tingitana* by the end of the century. There is little evidence of public building at this time, and what did occur appears to have been the initiative of emperors or imperial governors, not private individuals. The ceramic industry was likewise in a state of flux: production of Tunisian fineware, once common throughout Italy, ceased, but other centers of production arose.

The rule of Diocletian (284–305 CE) resolved North Africa's third-century crisis and revised the organization and administration of the provinces. The region was first contracted: following the outbreak of warfare in southern *Mauretania Tingitana*, the province was largely abandoned and what remained was left to Spain. The remaining provinces were subdivided: *Mauretania Caesariensis* became *Mauretania Sitifensis* and *Mauretania Caesariensis*; *Numidia* was divided between *Numidia Cirtensis* in the north and *Militiana* in the south, only to be reunited in 314 CE; *Africa Proconsularis* became *Zeugitana* in the north, *Byzacena* in the south, and *Tripolitania* in western Libya. The provinces were then brought together under imperial control and formed the *dioecesis Africae*. Governors of senatorial rank continued to supervise the proconsular provinces, which initially included *Zeugitana* only but later the reunited *Numidia* (c. 320 CE) and *Byzacena* (c. 340 CE). The other provinces were governed by a *vicarius*, an official of equestrian rank with a general supervisory role, who was answerable to the emperor.

The reforms of Diocletian initially left the armies of North Africa under the control of *praesides*, provincial governors of equestrian rank, who were in turn supervised by the *vicarius*. By the mid-fourth century CE, however, the civil and military functions of these governors were increasingly separated, and control of the armed forces became the responsibility of military specialists, *duces* and *comites* (dukes and counts), who were often of equestrian rank. The *praesides* remained the civilian governors of the provinces without proconsular rank.

The increasing centralization of power that occurred in the fourth and early fifth centuries CE brought with it the growth of an imperial bureaucracy that in many ways supplanted the judicial, financial, and administrative duties of local city magistrates. In particular, imperial officials were now responsible for the assessment and collection of taxes, a lucrative job that allowed its officers to finance public building projects. There were approximately 20,000 open positions in the imperial administration, many of which were short-term and granted senatorial rank to its officers; as a result of which, participation in the imperial bureaucracy was not only desired but required for the ambitious local elite. Nevertheless, the cities of North Africa continued to prosper, since many of these new senators retained close ties with their home communities. Under their jurisdiction many civic buildings were renovated, including *fora*, amphitheaters, bathhouses, and theaters. Moreover, since these new senators

were no longer required to own land in Italy, many began inhabiting their landed estates; a large number of villas with elaborate decoration dominate the coast and country of North Africa during this period. Only the far western and eastern portions of North Africa seem to have suffered at this time: Volubilis in *Mauretania Tingitana* was no longer part of the empire, and Lepcis Magna was subject to a number of attacks by Libyan tribes from which it never recovered.

The Christian community of North Africa grew significantly over the course of the second and third centuries CE but emerged in the early fourth as a substantial and divided one. The Great Persecution of 303 CE, issued by Diocletian, led a number of clergy members to hand over church scriptures to their city officials. These men became known as *traditores* and were required to undergo penance and a second baptism before readmission into the church. Moreover, their previous sacraments were rendered invalid. Thus, when, in 311 CE, a new bishop of Carthage, Caecilianus, was ordained without the consultation of the Numidian bishops, the latter claimed that Caecilianus was ordained by a *traditor* and his appointment invalid. The Numidian bishops, moreover, elected their own bishop of Carthage, first Maiorinus, then Donatus, who gave his name to the rival sect.

There now existed two opposing churches in Africa, the Catholics and the so-called Donatists, which created a schism that lasted until the early fifth century CE. During this time both churches maintained a separate administration, ordained a separate bishop, and upheld different policies, including those on the redemption of the *traditores*. Although church councils, official investigations, and the imperial government supported the Catholics, the Donatists continued to expand, particularly in the inland regions of *Africa*, *Byzacena*, and *Numidia*. Persecutions of the Donatists were sporadic and did nothing to quell the movement; the exile of Donatus in 355 CE only temporarily slowed Donatist growth, and by the late fourth century, the church had more than 300 bishops, support of most rural populations, and fidelity of many in the towns. By 420 CE, however, the Donatist church was more or less defeated when the Catholic church successfully implicated the Donatists in a series of military revolts and the imperial government declared Donatism heresy (405 CE), even illegal (in 411 CE). Both churches were to be united, Donatist clergy exiled, Donatists fined, and their property confiscated.

The Vandal invasion of 429 CE, however, brought an end to this religious conflict as well as Roman rule in North Africa. Over the course of the next 10 years, the Vandals took control of *Proconsularis*, *Byzacena*, and eastern *Numidia*; Carthage fell in 439 CE. Western *Numidia*, *Tripolitania*, and the *Mauretania* were occupied by 455 CE. The Vandals confiscated properties throughout *Proconsularis*, exiled or enslaved their landowners (of whom a large number were senators and other imperial officials), and distributed the land to Vandal followers. In the remaining provinces, landowners could retain their estates so long as they paid taxes. By the end of the fifth century CE, the Vandal kings, in an attempt to make Arian Christianity the official religion, exiled Catholic and Donatist bishops.

Despite changes in government, the African provinces prospered under Vandal rule. The region was now governed by a king to whom *comites* (companions), royal notaries, and Arian bishops were answerable, but civilian and municipal administration functioned without substantial change. The end of the *annona* to Italy and a flourishing in the Tunisian fineware industry brought a significant amount of wealth to the region. Exports of North African amphorae increased throughout the Mediterranean. Baths and churches continued to be constructed and maintained; a wide array of literary works were being produced.

Economic and political activity at this time was concentrated in towns and other rural settlements, a pattern mirrored in the increasing ruralization of urban centers. There is no visible decrease in the population of towns and rural settlements, but a number of cities appear to have suffered significant contraction and, in the case of Lepcis Magna, abandonment. In the cities, *fora*, temples, and

theaters were no longer used for their original purposes; some *fora* even became areas for pressing olives. The Roman administration gradually became decentralized and was eventually superseded by the authority of the tribes. Indeed, the most prosperous regions were those that depended less on interactions with the Mediterranean world and more on those with Romano-Libyan tribes. These Romano-Libyans, who came to control much of southern *Numidia* and both *Mauretania* by the early sixth century, were contributors to a new regional trade based on the intensive agricultural cultivation of their territory.

The Byzantine invasion of 533 CE removed Vandal kings from the seat of authority in North Africa, replacing them with the Byzantine emperor. A brief period of prosperity followed, during which time the emperor founded two new cities and began building campaigns in existing ones. Catholic bishops recovered their positions and privileges, churches were reconstructed and refurbished, and certain estates were returned to their Roman landowners.

The situation reversed in the mid-sixth century CE, due to a succession of natural, political, and religious crises. An outbreak of plague in 542 CE was followed shortly thereafter by an agricultural disaster; two years later, a Libyan revolt spread throughout *Tripolitania*, *Byzacena*, and southern *Numidia*; and, in the same year, a new schism divided the churches of Africa, Constantinople, and Rome. Similar disruptions are visible in the economy and archaeology of the region. The production of fineware decreased substantially and, in Tunisia and eastern Algeria, at least, was discontinued. Exports from North Africa became rare, and what little trade remained was directed eastward. Settlement patterns changed significantly: in the cities, amphitheaters and circuses were no longer used, luxury villas were transformed into farms, and cemeteries replaced urban centers. Forts and Christian basilicas were the only new constructions but were more Byzantine in style. By the end of the sixth century, however, a series of attacks led by the Arabs effectively brought an end to whatever traces of *Romanitas* and Christianity remained and introduced Islam to the area.

Key Issues/Current Debates

The mechanisms of imperialism and approaches to identity are at the center of current scholarly debates, concerning what it meant to be Roman in North Africa. Cultural exchange is no longer viewed as the active enforcement of the dominant power and passive acceptance (or aggressive resistance) of the subject; rather, it is generally accepted as the reciprocal transfer of culture and ideas, which varies according to region. The number of Roman public buildings and inscriptions throughout urban and rural settlements in North Africa attests to enthusiastic support of Roman culture, but the contemporaneous presence of Neo-Punic inscriptions and private monuments in indigenous styles points to the survival of local traditions (Mattingly 1995, 2004; Fentress 2006).

This then poses the questions of who engaged in these activities, what they stood to gain, and why? It is generally agreed that, at least in other provinces of the empire, the greatest level of compliance and adoption took place among the highest levels of society, that is, the ruling elite. The local, provincial elites were active agents in the adoption of Roman culture, while the lower classes became involved through emulation of their superiors. The subject remains understudied in North Africa, however (Mattingly 2011). Some studies accept the outright Romanization of the area (Picard 1990), while others see the provincial elite as recipients (Thébert 1978) or resistors (Bénabou 1976). The extent to which the lower classes participated, particularly in rural areas, is also uncertain. Whatever the case, it is important to allow for significant variability within and between different groups and in different regions (Mattingly 2011).

The study of economic history occupies a central position in current scholarship, questioning the extent to which Roman North Africa contributed to the economy of the empire (Wilson 2002; Dossey 2010). It also asks how the economy operated on local, provincial, and empire-wide levels, what were the primary industries, and who were the proponents of this activity. The Roman North African economy seems to have

been largely agricultural: Rome, in the early empire, formulated an economic policy in order to exploit the resources of the provinces for the long-term needs of the empire. In *Africa Proconsularis*, the imperial administration promoted intensive agricultural cultivation by leasing out imperial land to small-scale farmers, offering incentives for them to farm as intensively as possible, and overseeing their management through a group of middlemen (Kehoe 1988). More recently, scholars have examined the contributions of economies beyond agriculture, including ceramic (Hayes 1972; Carandini 1983; Peña 1998), olive oil (Mattingly 1985), and textile industries (Wilson 2001). While the presence of African Red Slip ware and amphorae throughout the Mediterranean, in addition to the number of olive presses throughout the African hinterland, suggests a highly diversified and vibrant local and empire-wide economy, it remains uncertain to what degree this matched the importance of agriculture.

The diversity of funerary architecture and its occupation of the Roman North African landscape have long attracted the attention of scholars. A number of tomb types have been identified and classified throughout Africa's long history, including *haouanet* (rock-cut tombs), *cupulae* (barrel-vaulted monoliths), and tower mausolea. Recently, however, scholars have focused on how these tombs and their associated rituals were connected to particular landscapes (Stone and Stirling 2007). It examines how individuals incorporated both local environment and funerary monument to communicate ideas of property rights, identity, and ritual behavior. What is more, the study of funerary rituals and monuments offers one of the best means through which to study displays of cultural identity, particularly in a region such as North Africa, which witnessed successive changes in dominant powers.

International Perspectives

The majority of research undertaken on the Roman history and archaeology of North Africa has been from a distinctly colonialist perspective (Mattingly 2011). From the French and Italian excavations of the nineteenth century to the more recent work of American and British scholars, outsiders have historically determined the region's Roman past. This is due in large part to the French and Italian appropriation of Roman history as their own; they believed themselves successors to this portion of the Roman Empire and even imitated imperial accomplishments. To that end, indigenous culture was discredited and viewed as a passive, if not rebellious, recipient of superior, foreign regimes (Gsell 1933; Munzi 2001). When Maghrebian scholars entered the discussion in the 1970s, they highlighted indigenous cultural (as opposed to military) resistance to Roman influence (Benabou 1976; Leveau 1978). While neither extreme is currently propounded, North African history continues to be approached primarily as a history of other peoples in the region (Punic, Roman, Vandal, Byzantine, Arab, and so on). Only very recently have scholars focused on the activities of the indigenous and nonelite peoples, which have revealed them as innovators of agricultural technology, agents in the economy, assimilators of Roman culture, and members of highly stratified social networks in their own right. While this research has made significant contributions to understanding North Africa's Roman history, it is necessary to pursue aspects of the Romano-African culture, in particular, and reintegrate them into the cultural heritage of Morocco, Tunisia, Algeria, and Libya (Mattingly 2011).

Future Directions

Of particular significance in future studies of Roman North Africa is the analysis of Roman imperialism and its effect on local, indigenous societies (Mattingly 2011). Rather than understand the empire simply from the "ruler and subject" point of view, this approach explores the various effects and experiences encountered at all levels of society. It questions the extent to which the imperial center is the agent of this change; likewise, it asks how subordinate

populations experienced empire and how this was manifest in their behavior and material culture. Cultural change, then, is viewed as the coexistence and exchange of values between indigenous cultures and prevailing power. It does not ignore the voices of the elite presented in contemporary literary sources, but supplements them, primarily through material culture, with the remaining subject population.

Postcolonial approaches to the study of Roman imperialism may have the most far-reaching impact in this field (Mattingly 2011). Postcolonialism, which concerns the effects of colonialism and colonization, has gained ground in historical research on empire from different periods and regions; it emphasizes the new identities created and negotiated both at the limits and in the center of empire. Given the abundance of archaeological evidence attesting to the activities of the elite (senatorial, provincial, and local), military communities, and subject peoples, Roman North Africa seems well suited to this approach. Likewise, the presence of contemporary Roman, Punic, and Libyan ethnicities (and combinations thereof) contributes to what must have been a fairly heterogeneous part of the empire.

Roman Africa is relevant to the field of economic studies, which is important for understanding the urbanization and functioning of the empire, in particular the study of commodities and their contribution to the imperial economy. Studies in the production and distribution of commodities, such as pottery, amphorae, olive oil, marble, mosaics, and textiles, have gone some way in illustrating the diversity of the Roman economy (though primarily agricultural) and the relationships between local, regional, and long-distance trade systems. Patterns of consumption are necessary, however, in order to better understand what proportion of the population benefitted from this economic production. In particular, analysis of patterns of consumption in rural and urban settings permits the identification of different settlement types; this, in turn, allows for diachronic comparison of settlements on a regional and empire-wide basis.

North Africa: Historical Archaeology

Ian B. Straughn
Brown University, Providence, RI, USA

Introduction

The archaeological investigation of North Africa emerges in the late nineteenth and early twentieth centuries in coordination with European colonial projects across the region as part of the expansion of classical and Orientalist scholarship into the study of sites along the southern Mediterranean coast. French, German, and to some extent British and American expeditions dominated the countries of Morocco, Algeria, and Tunisia well into the postcolonial period, while Italian-led excavations proliferated in Libya. It has only been since the latter part of the twentieth century that the archaeological services of the various independent states have asserted local control over the archaeological record within their borders. The case of Libya is somewhat exceptional in the wake of decades-long sanctions that led to the near cessation of foreign missions to its many sites. Similarly political unrest in Algeria at times has drastically reduced the contributions of international teams. It is still too early to predict how the landscape for a renewed archaeological involvement in several of these countries will change following the protest movements which took place in various North African states in 2011–2012, some resulting in the ousting of long-held dictatorial regimes.

During the first century of scientific excavations, most work was concentrated on the classical period cities of the North African littoral. This is hardly unsurprising given the scholarly agenda of most Euro-American scholars for whom North Africa's importance in world history only begins largely as a result of the Phoenician and later Roman colonization which established an impressive network of roads and cities all along the southern rim of the Mediterranean. This process of urbanization, the establishment of far-flung trade networks, and later the workings of Roman imperialism often served as ideological support for the new European colonizers who sought to establish what they saw as a similar *missioncivilatrice* in the various regions of North Africa. That sentiment is neatly captured in an address to French army officers in Morocco in 1925 where one official advised them to let the indigenes know "that we Roman were here before the Arabs" (cited in MacKendric 1980: 319). Unsurprisingly under these ideological circumstances, archaeological work has concentrated most heavily on the great classical period cities

such as Carthage, Leptis Magna, Timgad, and Volubilis as a demonstration of the grandeur and accomplishments of a colonial settler society that had turned the region into an agriculturally productive, imperial engine. More recently archaeological work of the classical period has begun to examine the relationship of these colonial centers to a largely indigenous rural hinterland in an effort to understand the impact of Carthage, Rome, and Byzantium on the substrate "tribal" societies.

Despite the early emphasis placed on the classical period during European colonialism of North Africa, the early twentieth century saw some limited efforts to conduct archaeological research on the postclassical era particularly for the region's seventh-century transition from a Byzantine domain to one under Arabo-Islamic control. As with the work of classical period scholars, questions regarding the processes of urbanization and imperial settlement and control continued to dominate research programs. French archaeologists in particular were occupied with developing an ideal typical notion of the "Islamic city." Indeed, the cities of North Africa, both living and ruined, became the prototypes both for an essentialized Islamic period urbanism and notions of space as fixed by Islamic principles.

Definition

The geographical limits of North Africa defy precise demarcation but have largely been agreed upon to include the region stretching from the Atlantic coast of Morocco to the western desert of Egypt. It extends from the southern Mediterranean into the largely uninhabited zones of the Sahara desert. Demographically the vast majority of the peoples of this region were to be found either along the coast, where seasonal rains allow for reasonably predictable agricultural production, or in various mountain ranges that offer both protection and possibilities for animal husbandry, control of trade routes, and other economic opportunities related to natural resources. Additionally, small population pockets are to be found in a handful of oasis settlements. Traditionally, Egypt has not been included in the historical or archaeological study of North Africa, with early European scholars referring to the region as Barbary of Africa minor. It is somewhat complicated to justify this exclusion particularly given that various imperial polities that ruled the Nile valley also exerted control over parts of Cyrenaica, the modern-day eastern Libyan coast. Similarly, an oasis settlement such as Siwa in the Egyptian western desert, both historically and to the present day, has a much stronger cultural affinity toward the ethnic Berber groups of North Africa than they do with the peoples of the Nile. Early Islamic geographers themselves were in disagreement about the exclusion of Egypt and the nature of the region's eastern border, and even one scholar of the tenth century CE, al-Muqaddasi, proposed the inclusion of Sicily and Spain into what was termed in Arabic as *al-Maghrib* (lit. the west or where the sun sets).

North Africa is dominated by a climate marked by hot dry summers with wetter cooler conditions in the winter months. The fringes of the Sahara are significantly more arid, while areas such as the Atlas Mountains tend to be more temperate than on the coast. These weather patterns have allowed the region to sustain cereal cultivation since the Neolithic, though annual rainfall variations can often lead to disastrous results. The economy has witnessed diversification through a long tradition of sheep and goat pastoralism, while both herder and agricultural livelihoods have together lead to destruction to woodlands that were once part of the landscape. In many ways this region is not at all dissimilar to other parts of the Mediterranean, one reason why it may have been attractive to colonists from the Levant, Greece, Italy, and elsewhere.

Key Issues

Phoenician and Roman Eras

Archaeological evidence for major settlements is lacking prior to the founding of the many colonial emporia which were initiated with the establishment of Carthage by the Phoenicians early in the first millennium BCE. Historical evidence for the indigenous populations is limited to references in

ancient sources to groups lumped together with the ethic term Libyes, although the nomenclature for the territorial locations of a handful of tribal confederations survives. The contemporary term "Berber," which is used to refer to North Africans who do not associate themselves as Arabs, is itself a corruption of the Greek epithet *barbaroi*, meaning non-Greek speakers. It is important to note that the archaeological study of these indigenous groups, whether nomads or settled farmers, has been secondary in most cases to the study of those outsiders who would transform the region through urbanization and imperial politics. An important exception is the Garamantes, first mentioned in Book IV of Herodotus' *History* and whose society and its archaeological signatures have become of focus of much research in recent decades.

Cities dominate the focus of most archaeological research projects in North Africa, none more so than the seminal site of Carthage, which has been excavated since the nineteenth century and with major projects undertaken as part of a campaign to save the site in the 1970s and 1980s under the auspices of UNESCO. Such concerted attention to this principal seat of Punic control, which ruled over much of North Africa for more than half a millennium prior to its final conquest by Rome in 146 BCE, has allowed archaeologists to reveal most of the city's main features. The ruins of ancient Carthage which span from its Phoenician inception through to the end of Byzantine control in the late seventh century CE are located in what are today the suburbs of Tunis, the modern capital of Tunisia. Excavations have revealed much of the town's citadel, known as the Byrsa, though its earliest occupation levels have been largely truncated by the transformation of the area by Roman period engineers. Other areas of major study have focused on the port of Carthage, the key to the city's role as a major Mediterranean trading hub that vied with Rome for control of that sea. The city was served by two harbors, one that was devoted to the military and the other to commercial operations, demonstrating the dual nature of the social context in which its inhabitants lived. Of its major urban institutions perhaps the most intriguing is that of the tophet, or precinct of Tanit, a religious sanctuary in which the citizens were known to practice various forms of ritual human infant and animal sacrifice. This open-air enclosure delimited by a temenos wall was filled with centuries of cremated urn burials which were surmounted by variously decorated stone markers. Similar sanctuaries of the Punic culture have been excavated at various other North African sites and were in use even into the Christian era.

While Carthage was certainly the most famous of the Phoenician settlements, it was by no means the only one; rather it was the center of a far-flung network of ports all along the North African coast and beyond. Of these Kerkouane is perhaps the most well preserved and archaeologically best documented with two main periods of occupation that were interrupted by an invasion from Sicily and with the town abandoned at the start of the Punic Wars with Rome. This was a walled town with a system of wide streets laid out orthogonally. Near the center of the urban landscape was a large courtyard structure with stone benches that may have served as a temple for an unknown cult. The archaeological record also indicates that this was a center for the production of the much famed purple dye of the Phoenicians, owing to the large quantities of Murex shells recovered from an area of the site that appears to have been an industrial zone of kilns and workshops. Further east lay the province of Tripolitania which was colonized in the seventh century BCE, taking its name from the region's three main urban foundations: Labdah/Leptis Magna, Sabratha, and Trablus/Oea. The region west of Carthage as far as Tangiers and even beyond exhibits numerous Phoenician coastal settlements that appear at roughly equal intervals. Archaeologists, taking note of this apparent uniform spacing, have suggested that this was designed to provide ports at a distance of about one day's sail (c. 30–40 km). While suggestive of the possibility that first millennium BCE traders operated a system similar to that of *cabotage* (short coastal sailing and trading known through documentary evidence from the early modern period), the chronology of many sites suggests they were somewhat later than the height of Phoenician power in the region.

The Roman conquest of Carthage, resulting in the city's brutal destruction, would nevertheless maintain and indeed expand this urban network begun by the Phoenician colonists. The transition to Roman rule and the status of various parts of North Africa as either directly controlled provinces or client kingdoms have left substantial traces in the archaeological record. The degree to which the southern Mediterranean underwent a process of Romanization, an analytical term deeply contested among classical archaeologists for its ability to capture the nature of the cultural, political, and economic interactions that developed with the construction of the vast Roman Empire, remains at the center of much research for this period. The archaeological record of life in Roman North Africa provides us with a large volume of data regarding the transformation of the region into a granary of the empire, for the new municipal intuitions and urban amenities, as well as the system of defenses that sought to ensure the productivity of its land and the safety of its cities. A major force in these changes was the Roman army which was responsible for extensive public works. Across the region the archaeological record is still replete with evidence of the roads, aqueducts, fortresses, and walls which imperial forces put in place. Urban landscapes became filled with theaters, baths, temples, nymphaea, and with the coming of Christianity as a state sanctioned religion all manner of ecclesiastical structures. The security situation, which was largely designed to make nomads sedentary and thus lessen their threat to urban centers, was so successful at times as to allow some towns, such as Cuicul and Teuchira in Cyrenaica to do without defensive walls.

The city, however, was not the only beneficiary of Roman rule. Imperial estates abounded as well as the privately owned *latifundia* for which Roman Africa had become famous. Archaeological surveys have shown that large swaths of previously unproductive land came under cultivation in many areas due to extensive walled terracing which would fall into disrepair and neglect after Rome withdrew and the Vandals moved in. To a certain degree, this would be resuscitated as the region was reorganized as a province of Byzantium. This productive land was the basis for an economy that supported large numbers of wealthy landowners and entrepreneurs who had the wealth to build large private residences throughout the region. These manors and estates have received much attention by archaeologists and art historians alike for their numerous fine floor mosaics depicting many aspects of Roman life in the province. This visual culture has suggested not only the prosperity which many segments of the society enjoyed but also their close ties to Roman cultural practices, even when inscriptional evidence suggests that the patron was of Punic origin.

The Coming of Islam

North Africa's emergence in the late seventh century as part of *Dar al-Islam* (lit. the house of Islam) following the conquests of the Arab-Muslim armies was to signal a profound change in course for this region. Of the most important transformations that this area entertained were the migration of large number of Arabs and other Easterners and the establishment of Islam and the Arabic language as major cultural forces. These long-term processes that do not really begin until well into the tenth century and later have largely been ignored by archaeological research and left to scholars of the textual record. What can be stated is that for the indigenous Berber populations, their incorporation within the expanding Muslim world would have a far more profound effect on their politics and culture than what was experienced during previous imperial interactions with either Rome or Carthage. The archaeological record of both cities and other sites has demonstrated major shifts in the kinds of material culture, economic lifeways, as well as social relations within communities. More specifically archaeological work has demonstrated that new trade networks developed that linked North Africa with the wider Near East, West Africa, and beyond. This region became the conduit for the major supply of commodities such as gold, ivory, and labor that came from other parts of the African continent. The manufacturing centers in Egypt and Iraq would in turn supply the growing city states and minor principalities across

the *Maghrib* with luxury goods ranging from ceramics to new plant species originating from the Indian subcontinent. A good example of these interconnections and their material culture correlates can be found in the archaeology of the Moroccan site of Sijilmasa, a major caravan station for the gold trade.

The Orientalist notion of the quintessential "Islamic city" has been widely influential for much of the early archaeological work that analyzed the record of the Islamic periods in North Africa. In many ways this is a continuation of classical archaeology's fascination with urban landscapes and an effort to articulate an abrupt rupture between the periods of late antiquity and Islam. This project has become increasingly more nuanced in recent decades with work at a multitude of sites, including costal redoubts (*rabitat*, s. *ribat* in Arabic) such as Monastir and Sousse demonstrating elements of both continuity with the existing built environment and aspects of adaptation to changed political and cultural climates.

Questions of empire and imperial control continue to play a role in archaeological investigations as North Africa enters into the early modern period. Excavations at the site of Qsar es-Seghir in northern Morocco are an early example of global historical archaeology particularly as it relates to the development of the European colonial enterprise. In this case excavators revealed the impact of Portuguese colonial expansion beginning with Henry the Navigator in the fifteenth century. The project also initiated a regional archaeological survey that tackled questions of smaller scale urban settlement patterns that demonstrated the role of larger political forces and imperial integrations in shaping the organization of settlement hierarchies.

Future Directions

As the archaeology of North Africa enters the twenty-first century, it faces a number of uncertainties and challenges as well as opportunities. While much of the future of archaeology in this region will be shaped by the rapidly changing political climate and the amount of resources that governments and other funders are willing to expend on the rich heritage of their territories, there continues to be a strong local interest in studying the various pasts which the archaeological record can reveal. Despite this desire to sponsor archaeological work, many sites are threatened by rapid urban expansion, the consequences of political turmoil, worsening environmental conditions, and the general perception that the field of archaeology is less prestigious or lucrative than other professions and thus unattractive as a career option. Regardless, partnerships between local and foreign scholars continue to build on the work of previous generations often despite of a legacy of colonial and Orientalist attitudes that have guided much of that previous scholarship and practice in the field.

North America (USA and Canada): Museums

Alex Barker
Museum of Art and Archaeology, University of Missouri, Columbia, MO, USA

Introduction

Museums of archaeology in North America include at least three distinct kinds of entities: (1) museums in the strict sense, combining maintenance and care for permanent archaeological collections with their public interpretation; (2) science or interpretive centers, which interpret archaeological knowledge and material evidence of the past but do not hold or curate permanent collections; and (3) repositories, which care for collections but do not embrace a public education or interpretive role.

Taken as a whole, museums play a crucial role both in preserving material evidence of humankind for the benefit of future generations and in interpreting that past for broad public audiences. Their potential to increase knowledge regarding the past is considerable – a survey in 2000 found that 88% of American adults had visited museums interpreting archaeological materials (Fig. 1). It is less clear that this potential has been fully realized; that same survey found that less than 10% reported learning about archaeology from those visits (Ramos and Duganne 2000).

Today there are some 34,000 museums in the USA and Canada, but the precise number holding archaeological collections, and the scale of those collections, is not known. By any measure, however, the scale is immense. In fiscal year 2019, estimates of US federal collections were more than 82 million objects, not including more than 52,000 linear feet of associated documentation and records (or the collections of the Smithsonian Institution). Harvard's Peabody Museum of Archaeology and Ethnography holds more than

North America (USA and Canada): Museums, Fig. 1 Museums can play a profound role in educating the public about both the past and its study, largely by allowing the public to engage with authentic objects and better understand their importance in archaeological inference. (Milwaukee Public Museum; Photo Alex W. Barker)

1.2 million catalogued objects and more than half a million photographic images, while the Canadian Museum of Civilization holds some three million objects.

This entry deals primarily with North American museums as archaeological institutions. For entries regarding museum representation and critical approaches to museum interpretation, see the entries "▶ Museums and the Distortion of Archaeology for Political Purposes" and "▶ Museums and Memory Experiences," in this encyclopedia.

Definition

Within the United States, museums are defined by statute as a public or private nonprofit agency or institution organized on a permanent basis for essentially educational or aesthetic purposes which, utilizing a professional staff, owns or utilizes tangible objects, cares for them, and exhibits them to the public on a regular basis. In Canada, museums are similarly defined as permanent, not-for-profit institutions that acquire, preserve, research, interpret, and exhibit the tangible and intangible evidence of society and nature, whose exhibits are regularly open to the general public. Both the American Alliance of Museums (AAM, until 2012 the American Association of Museums) and the Canadian Museums Association (CMA) broaden these definitions somewhat to include entities that do not manage collections (science centers), and within the USA in particular, there are a range of repositories which manage collections with limited or no public exhibition or interpretation.

Relatively few museums in the USA and Canada are dedicated exclusively to archaeology (Fig. 2). Some include ethnology and anthropology more broadly (e.g., the US National Museum of the American Indian, the Peabody Museum of Archaeology and Ethnology, the Arizona State Museum, or the Canadian Museum of Civilization), while others include archaeology within a broader set of disciplines within natural history (e.g., the American Museum of Natural History, the Smithsonian's National Museum of Natural History, the Field Museum of Natural History, the Denver Museum of Nature and Science, the Royal Alberta Museum, or the Natural History Museum of Los Angeles County) or general museums (e.g., the Glenbow Museum, the Royal Ontario Museum, or the Milwaukee Public Museum). More recently museums created and managed by Native communities have been developed (e.g., Alutiiq Museum and Heritage Center, Mashantucket Pequot Museum and Research Center, Ksan Historical Village and

North America (USA and Canada): Museums, Fig. 2 Yukon Beringia Interpretive Centre, a noncollecting institution, interprets the archaeology and paleoecology of the "land bridge" once connecting the Old and New worlds. Museum, Aanischaaukamikw Cree Cultural Institute, Huhugam Heritage Center) interpreting the past from the standpoint of indigenous communities.

Other museums (e.g., the Metropolitan Museum of Art, the Cleveland Museum of Art, or the Getty Museum and Villa) hold archaeological objects but manage and interpret them exclusively as works of art. Museum ethical standards, particularly within the USA, reflect a tension between these aesthetic vs. anthropological approaches, with museums managing objects as works of art often arguing for less rigorous requirements regarding provenance and legal export. Essentially this reflects a valorization of essential qualities of individual objects on the one hand, and their significance, context, and potential to inform understandings of social meanings and processes on the other.

Historical Background

In the nineteenth and early twentieth centuries, museums were the primary institutional settings for North American archaeology. Most of the great North American archaeological museums were founded during this period, and many amassed the bulk of both their collections and their stature prior to World War I. In the middle decades of the twentieth century, the primary context for Americanist archaeology shifted to universities, with the unintended effect of separating the creation and interpretation of archaeological collections from their curation and care. But while the intellectual focus shifted away from museums, this was also a period in which massive archaeological collections were generated through federally funded projects, creating and sometimes filling both freestanding and university-based museums and repositories. In some cases collections remained under the control of academic departments without explicit arrangements for longer-term care, creating legacy collections whose status and care remains a challenge. In the closing decades of the twentieth century and opening decades of the twenty-first century, those roles have further fragmented, with the majority of archaeological materials now being generated by cultural resource management (CRM) and contract-based archaeological projects (in Ontario, e.g., it is estimated that 80–90% of all archaeological fieldwork is contract-based CRM work). This fragmentation has led to a separation between the archaeologists conducting the bulk of fieldwork and the resultant collections (archaeologists in CRM), the substantive scholarly and grant-funded research based on fieldwork and collections (archaeologists in higher education), and the management, care, and stewardship of those collections (archaeologists in museums). Lack of coordination between the three sectors has resulted in rapidly growing collections whose research value is largely unknown, and may result in additional fieldwork on questions which could be effectively addressed by extant data already in repositories and museums.

By the late 1970s, a "curation crisis" had been recognized, with museums lacking the space, funding, and staff to adequately deal with burgeoning collections resulting from CRM compliance. Museums and repositories were to have been integral parts of heritage management from its inception; the 1906 US Antiquities Code required that objects collected be placed in public museums and permits were to designate a publicly accessible repository. In more recent years, CRM projects have included curation fees for the management and care of collections resulting from compliance activities, but for the most part, these have been simple fee-for-service arrangements not based on the research value of the collections themselves.

Several important trends emerged in the late 1980s and early 1990s. Thoughtful approaches to the ethics of collecting the cultural property of indigenous communities (e.g., Messenger 1989), critical studies of museums as institutions and their representation of the other (e.g., Karp and Levine 1991), and increased attention to the impact of museum acquisitions on antiquities trafficking and site looting (e.g., Tubb 1995) all changed and enriched discourse in museum archaeology. These trends have continued and accelerated in the opening decades of the twenty-first century.

At the same time, Native concerns over both the way their cultures were represented in and cultural property and human remains appropriated

by museums came to the fore. In the USA, these concerns led to the Native American Graves Protection and Repatriation Act (NAGPRA) and the National Museum of the American Indian Act. These laws allowed Native communities to reclaim human remains and four categories of objects from museums based on cultural affiliation: (1) funerary objects associated with human remains in a museum's collection; (2) funerary objects not associated with human remains in a museum's collection; (3) objects of cultural patrimony; and (4) sacred objects. In Canada, the Task Force on Museums and First Peoples was created to address concerns raised by a Glenbow Museum exhibition organized to coincide with 1988 Calgary Olympic Games. Native communities found the original title, layout content, and sponsorship inappropriate, and these concerns led to the Task Force's recommendations which have permanently altered the relationship between First Peoples and Canadian museums.

Key Issues/Current Debates

Curation Crisis

No resolution to the ongoing "curation crisis" has yet been offered (Bawaya 2007). New or expanded federal repositories in the USA and Canada address some shorter-term aspects of the curation crisis, but do not address the needs of nonfederal museums, repositories, tribal museums, or university museums. The rate of compliance activities and the resulting growth of collections continue apace (Fig. 3), without equivalent increases in government or private support for curatorial activities. While the rate of compliance-related collections growth at the Canadian Museum of Civilization has slowed, it has increased correspondingly at provincial and territorial museums. Government support for museums continues to decrease both as appropriations for governmental museums and repositories and as grants for nongovernmental entities. The US National Science Foundation no longer supports curatorial activities or collections improvement grants, and both restructuring of Canadian museums and reduced support for both Canadian museums and agencies that support museums place further stresses on overstretched staff. And while many aspects of legal or ethical mandates for repatriation and consultation are valuable and long overdue, they further overextend museums which had already been recognized as understaffed, underfunded, and overcrowded prior to these mandates. This is essentially a funding issue and is unlikely to be resolved in the near term.

NAGPRA and Repatriation

NAGPRA has had significant effects on American museums, most positive. Canadian repatriation

North America (USA and Canada): Museums, Fig. 3 Archaeological collections from compliance activities continue to grow at a faster rate than funding for their curation. (University of Missouri Museum Support Center; Photo Alex W. Barker)

protocols based on recommendations of the Task Force on Museums and First Peoples lack the force of law, but are accepted by all major Canadian museums. Consultation with Native communities has increased, summaries and inventories have improved intellectual control over many categories of archaeological materials and remains, and a range of collaborative research and interpretive projects have been developed. An increasing number of curators in anthropology and archaeology museums have built successful academic careers by working with Native communities and making those relationships the basis and subject of their scholarly study. While the costs of NAGPRA compliance were a considerable concern in the years following passage of the Act, most museums have now adjusted their staffing levels and expectations to accommodate compliance activities. Most current concerns regarding NAGPRA involve the disposition of human remains whose cultural affiliation cannot be determined. Recent regulatory changes (codified under US federal regulations as 43CFR10.11) mandate the disposition of human remains to claimant groups even if there is no evidence that they are culturally affiliated to the remains themselves; some museum and scientific organizations have expressed concern that this provision conflicts with the Act's original intent.

While both NAGPRA and the recommendations of the Task Force on Museums and First Peoples have had generally positive impacts on the relations between museums and the communities they study, they privilege certain kinds of research at the expense of others. Legal and voluntary restrictions on the analysis of human remains have had a clear and continuing effect on scientific studies of the human past; since North American museums hold human remains from other areas of the world as well, one outcome has been that archaeologists and physical anthropologists are able to better address questions regarding the human career in some geographical areas but in others must leave them unaddressed.

Conservation

Scientific advances in conservation have greatly improved our knowledge of how to preserve and protect cultural collections. In part this has resulted in better understanding of environmental factors and preventative care (Elkin and Norris 2019), and in part in improved interventions for conserving and stabilizing individual objects. Along with these advances has come an increased appreciation of the effects of older chemical treatments, particularly the use of arsenical and mercuric compounds, on modern collections (Charola and Koestler 2010). The contaminants limit the utility and accessibility of some older organic collections. Repatriation of contaminated objects is a significant and well-documented problem, particularly for objects being repatriated because they are required for continuing religious purposes. A growing body of literature deals with both the identification and amelioration of contaminants, and helping claimant communities manage risks associated with these objects.

As museums have become more sensitive to the concerns of Native communities (Clavir 2002), conservation approaches have changed to accommodate respectful treatment including the inclusion of sacred plants, orientation of objects, organization of collections, and the performance of necessary ceremonies. In some cases these protocols contradict conservation guidelines based exclusively on preservation and reflect a more inclusive approach to stewardship (Ogden 2004).

Museums and Unprovenanced Collections

In April 1970 the University of Pennsylvania Museum of Archaeology and Anthropology issued the Pennsylvania Declaration, which affirmed that the Museum would purchase no antiquities for its collections unless accompanied by a provenance "pedigree" – the first major market country museum to take such a position. Shortly thereafter the UNESCO Convention on the Means of Prohibiting and Preventing the Illicit Import, Export, and Transfer of Ownership of Cultural Property was signed. The 1970 date for the UNESCO Convention has become an ethical touchstone for many US museums (Canadian law prohibits the importation of cultural objects unless legally exported from their country of origin). The Association of Art Museum Directors (a US-based organization limited to the directors of the

200 largest art museums) had previously established guidelines allowing the purchase of antiquities by museums if it could be shown that objects had left their country of origin at least 10 years before. Numerous archaeological organizations (including the Society for American Archaeology, the Archaeological Institute of America, the American Anthropological Association, and the Council for Museum Anthropology) raised strong concerns that these guidelines served less to prevent site looting than to regularize it. In 2008 both AAMD and AAM released revised standards for the acquisition of antiquities. Both organizations required museums to obtain documentation that objects had either left their source countries before the date of the UNESCO Convention or that they had been legally imported; AAM guidelines went considerably further by requiring that objects also have been legally exported from their country of origin, a much more stringent standard. In recent years AAMD restrictions have lessened, with a larger number of objects with incomplete provenance being accepted by US art museums.

Deaccessioning

In addition to the restrictions on the acquisition of archaeological material previously noted, once antiquities enter the US or Canadian museum collections, they are subject to additional restrictions on any future use. Federally associated collections or collections in federal repositories cannot generally be culled by deaccession (removed from permanent collections) under current US regulations, creating a problematic situation where collections may be culled or limited as part of the research design or field component of research, but once they are transferred to a museum or repository no deaccession or management by culling is allowed. Currently there are initiatives to allow such deaccessioning under specific conditions similar to those used by nonfederal museums, but they have not yet been adopted. Normally reasons for deaccessioning include lack of relevance to the institution's scope, limited or negligible value for study, duplication (both of the foregoing usually applying to works of art rather than research collections), poor condition or deterioration beyond the point at which conservation is feasible, determination that the object is a fake or forgery, determination that the museum does not and cannot hold good title, or a valid repatriation claim. In addition to any ethical restrictions on sale of antiquities, museum ethics restrict the use of any proceeds from the sale of deaccessioned objects of any kind to the acquisition of more representative or useful objects, preferably in the same collections area. AAM guidelines also allow funds to be used for the specific conservation of objects within the collection, narrowly defined. Under no circumstances may the proceeds be used for general operations. Several university-based museums have violated these guidelines in recent years, including Brandeis University, which sought to deaccession and sell its collections to make up for market losses to its university endowments, and Fisk University, which agreed to sell collections objects for operating funds in violation of both applicable ethics codes and restrictions of the original donor.

Virtual Data and Physical Objects

While broad metadata standards for archaeological data exist (the Dublin Core and its various extensions including the Darwin Core for biological materials, CIDOC, and the associated ISO 21127 standard), they are neither fully embraced nor systematically applied. The conceptual complexity of some of these data models adds to the challenge of systematic implementation; CIDOC 5.0.1, for example, includes 86 classes and 137 properties (and their inverses) as part of its schema. In 2011 the US National Science Foundation solicited white papers identifying "big questions" or pressing needs in the social and behavioral sciences – issues that could allow major advances in research with the infusion of significant funding. One of the needs identified (and endorsed by the American Anthropological Association) was a systematic survey and inventory of all of the cultural holdings already housed in American museums, repositories, and institutions of higher education. Artifacts Canada, an initiative of the Canadian Heritage Information Network (CHIN), already allows the public limited search access to some four million selected objects in Canadian museums.

The expansion of Canadian and US Museum Studies programs in the late twentieth century – and of online version of these programs in the twenty-first century, making them more accessible to smaller museums, tribal museums, and affordable to nontraditional scholars – has increased the professionalism and working knowledge of many entry-level museum staff, as well as honing and updating the skills of more senior staff. Much of this training focuses on interpretation and the stewardship of physical things, including both paper records and collections objects. The emerging demands of electronic resources and collections are quite different, and museum organizations (CMA, AAM, CHIN) and funders like the US Institute for Museum and Library Services and National Endowment for the Humanities have increasingly focused on training new museum professionals to meet the changing demands of digital collections (CHIPs Workshop Report 2008).

Institutional efforts to capture and maintain digital archaeological archives are already underway. In Canada, the Sustainable Archaeology program at Western and McMaster universities serves as a cooperative for the archiving of both physical and digital archaeological data on a fee-for-service basis. First Nations communities are active partners in developing management and access standards. In the USA, the Digital Archaeological Record (tDAR) serves as an international archive for digital data relating to archaeological investigations and scholarship, focusing primarily on sustainable archiving and the specific requirements of digital curation. The Alexandria Archive Institute, another US-based entity, focuses on open access scholarly communication and data sharing through digital access. In 2019 the American Anthropological Association launched the Open Anthropology Research Repository (OARR), an open access, discipline-specific platform for sharing and archiving research and documents.

Scholarly Status of Curatorial Activities

With the shift from the museum to the academy as the primary venue for substantive archaeological research in North America came changes in the ways in which scholarly productivity was measured. In recent years museum anthropologists in the USA and Canada have worked to have curatorial activities unique to the museum field – organization of exhibitions, consultation with descendant communities, work as experts on cultural property issues, and other endeavors which may not lead to journal-based publication – recognized in promotion and tenure decisions. Efforts in this area were led by the Council for Museum Anthropology, a professional society within the American Anthropological Association. In 2012 AAA issued promotion guidelines for practicing professional anthropologists and archaeologists and also established expert review panels of practicing professionals to assist academic units in both promotion decisions and departmental program reviews (American Anthropological Association 2011).

Accreditation and Standards

Museum accreditation within the USA has been performed by the AAM through a separately established Accreditation Commission since the early 1970s and involves a combination of institutional self-study, review by Accreditation Commission staff, peer evaluation by a visiting committee of accreditation reviewers, and a final decision by the Commission. Accreditation has generally been for 10 years or less, although this was recently increased to 15 years as part of reorganization and streamlining of the accreditation process. As of 2019 1081 US and Canadian museums had achieved AAM accreditation.

Within Canada, the Canadian Association of Professional Conservators (CAPC) has had an active accreditation program in place since the early 1970s. Accreditation is based on a formal application with supporting credentials and documentation, followed by a peer evaluation conducted by a four-person Board of Examiners. The evaluation includes both general conservation knowledge and techniques/knowledge specific to the applicant's area of specialization. Within the USA the American Institute for the Conservation of Historic and Artistic Works (AIC) proposed an examination-based certification program, but the initiative was defeated in 2009 by a vote of the membership.

No accreditation or licensing mechanisms for other archaeological museum professionals are currently in place in either the USA or Canada.

International Perspectives

Archaeology as Anthropology

Unlike other continents, archaeology in North America has been traditionally viewed as a subdiscipline of anthropology with closer intellectual ties to ethnography than to either history or geology. Developing from museum contexts in which the material culture of communities both extant and extinct was being systematically organized, during periods in which there were few chronological controls, North American archaeology was heavily influenced by the direct historical approach (itself born in museum contexts) which constructed cultural chronologies by working backward from living communities into the prehistoric past. Organizational schema such as the Midwestern Taxonomic System – initially developed at the Milwaukee Public Museum in the 1930s – used material culture trait lists to organize archaeological assemblages relative to one another and to those of historic groups. While in many respects this anthropological approach has benefited North American archaeology, it also reflects a racial disconnect in which archaeology as anthropology divorces Native histories from broader national histories privileging European colonization at the expense of aboriginal occupations (Ames 1992).

Composition of the Archaeological Archive

Archaeological collections in North American museums and repositories generally include both physical objects from excavations as well as all associated records and documentation, in distinction from some other countries (e.g., Scotland and Wales, where objects are held by regional museums and records by their respective Royal Commissions for Ancient and Historic Monuments). Management of this larger archaeological archive is understood to begin with the research design stage, long before the initiation of fieldwork (e.g., Sullivan and Childs 2003), and most archaeological codes of ethics stress the equal importance of object and record.

International Treaties and Trafficking

While Canada and the USA are both source and market countries in the global antiquities trade, for the most part both are viewed as markets, legally allowing the commercial movement of objects illegally removed from their country of origin; in recent years applicable Canadian laws have reduced the import of unprovenanced or illegally exported cultural objects.

Museums in the USA and Canada are subject to several international treaties affecting their ability to acquire and accession objects. Both Canada and the USA are signatories to the 1970 UNESCO Convention on the Means of Prohibiting and Preventing the Illicit Import, Export, and Transfer of Ownership of Cultural Property, although the USA accepted only articles 7b and 9 and Canada's implementation focuses primarily on article 3. Implementation within the USA depends on negotiated memoranda of understanding between the USA and other signatories to the Convention, since ratification only 19 such memoranda have been completed (as of early 2020). In Canada both exports of cultural materials from Canada and imports of cultural property from source nations are controlled, but foreign governments seeking return of objects must compensate individuals or institutions who acquire objects without knowledge that they were acquired in violation of applicable law. Both the USA and Canada are also signatories to the 1954 Hague Convention for the Protection of Cultural Property in the Event of Armed Conflict; the USA formally ratified the Convention in 2008, more than 15 years after its promulgation. Neither the USA nor Canada is a signatory to the UNIDROIT Convention on Stolen or Illegally Exported Cultural Objects.

Ownership and Title

Property laws in Canada and the USA do not vest ownership of antiquities in the federal government unless the material originates from public lands. Similarly, and in contrast to some other parts of the world, Canada and the USA never

established a national museum system with a centralized administrative center supervising smaller regional museums. Different museums developed independently following quite distinct developmental trajectories, informed by a range of interests and concerns, and including museums organized as public charities or nonprofit corporations, arms of government (local, state/provincial, national, or tribal), or units within institutions of higher education, among others. Title and control over collections vary considerably across this range of institutional forms. Changing forms of governance has also complicated issues of title. Privatization of some previously city- or county-run institutions has led to different models for collections ownership. In some cases the nonprofit organization operating the museum assumes ownership for objects acquired after privatization; in other instances, the organization manages collections whose title is vested elsewhere.

Canadian museums generally receive a larger proportion of overall funding from government than do American museums. Nongovernmental museums in the USA reported in a 2008 survey that less than 24% of funding derived from government support at any level and most of that funding was targeted at science museums and science centers.

Within the USA one of the major changes affecting museum title in the latter part of the twentieth century was the development of the McClain doctrine, a set of legal principles holding that if a foreign nation state has well-defined and enforced laws vesting ownership of archaeological materials in the state, then that nation state has standing to bring legal action in US courts against looters and traffickers under the US National Stolen Property Act. While convictions under the doctrine have been few, and one recent case (between the St Louis Art Museum and the Egyptian government over a cartonnage funerary mask of Ka-Nefer-Nefer) has called into question how broadly the doctrine can be applied, McClain problematizes title for objects without clear provenance, making museums more sensitive to the need for adequate documentation prior to acquisition.

Future Directions

Achieving Balance Between Museum Functions

Early twentieth-century North American museum theorists like John Cotton Dana emphasized the public education rather than purely research role of museums. In a landmark 1992 report, *Excellence and Equity*, the American Association of Museums called on all museums to place education at the center of their public service role and make education part of all museum activities. North American museums continually rebalance and reexamine the resources allocated within museums for primary research and for public education; in more recent decades research allocations have also had to compete against the desire to attract more visitors to museums in order to increase earned revenues and leisure market share in an increasingly competitive environment (Fig. 4). Similarly, the rise of repositories holding collections on a fee-for-service basis has increased concerns that strategic growth of museum holdings based on long-term value may be compromised by short-term efforts to raise revenue through curation fees on the one hand or increased gate and visitor traffic on the other. Some curators find research becoming a residual activity – something they can do when or if the more pressing demands of public engagement, education, fundraising, and management allow. And while the curatorial function is central to the idea and character of the museum, it is not generally a revenue-generating position and is hence subject to close scrutiny during cycles of budget reductions.

Audience

In recent decades North American museums in general have increasingly focused on the needs of visitors. While generally positive, these efforts have led to increased demands on curators to engage in social media, fundraising, and public relations events which are aimed less at research or education in the formal sense than public engagement more broadly, which may erode the core curatorial functions. Partially countering this trend, archaeology museums have increasingly

North America (USA and Canada): Museums, Fig. 4 Over the course of the twentieth century, the primary emphasis of North American museums shifted from behind-the-scenes research and curation to public interpretation and engagement. (Canadian Museum of Civilization, Hull, Quebec, Canada. Photo by Taxiarchios228, http://commons.wikimedia.org/wiki/File:Gatineau_-_QC_-_Canadian_Museum_of_Civilization5.jpg. GNU Free Documentation License)

focused on the viewpoints and values of source communities, in part to undo stereotypes reified and perpetuated by previous generations of museum exhibitions and practices. This can create tensions between common models for museum interpretation which allow considerable latitude to the visitor in meaning-making and concerns of Native communities who wish to more clearly define how they are perceived and portrayed.

While many North American museums recognize the need to better serve and engage minority populations, few have successfully done so on a sustained and continuing basis. Minority populations constitute 34% of the US population, for example, but minority individuals represent only 9% of museum visitors. Demographic trends suggest that by sometime in the middle of the twenty-first century, minority groups will actually form the aggregate majority of the US population. While museums – and particularly anthropology and archaeology museums – have become increasingly sensitive to the interests of Native or source communities regarding core issues including rights, repatriation, and representation, they have generally been less responsive to the demands of other minority populations they serve as visitors, whose needs may be different from or in competition with the interests of Native communities.

At the same time, one of the fastest-growing areas within the broader museum community is "tribal" museums, created and managed by tribes, First Nations, or descendant Native communities (Fig. 5). Coupled with the expansion of tribal historic preservation programs and increasing number of Native peoples pursuing careers in anthropology and archaeology, this trend may profoundly change both the ways in which museums are perceived by descendant communities and the representational tropes by which Native peoples are depicted in museums generally. In a 2003 survey of 74 tribal museums, conducted by the American Association for State and Local History, "cultural preservation" and "role as a repository" were identified as a tribal museum's most important functions. The same survey indicated that the primary audience for most tribal museums was other tribal members (Abrams 2003).

Title

Accessioning reflects an assertion of title to collections, but several trends in cultural property law and ethics call into question aspects of the goodness of title many museums assume they enjoy. NAGPRA avoided constitutional challenge as a taking by asserting that museums never held good title to certain cultural collections in the first

North America (USA and Canada): Museums, Fig. 5 An important trend in the later twentieth and twenty-first century has been the rise of Native museums interpreting indigenous histories and identity through Native voices. (Photo by Elliot Schwartz for Studio EIS, http://en.wikipedia.org/wiki/File:StudioEIS_Mashantucket_Pequot_Museum.jpg. GNU Free Documentation License)

place. The McClain doctrine similarly questioned the clarity of title to certain kinds of cultural materials if good provenance was not proven. And although the recommendations of the Task Force on Museums and First Peoples do not impact issues of legal title, they do problematize the ethics of asserting title to certain categories of material. Broader issues of image rights and intangible property are likely to become more sharply defined in coming decades, undermining nineteenth-century Lockean constructions of museum collections as private property. A gradual shift is thus likely from management of collections based primarily on legal title or ownership of objects to management based on defined rights and agreements, with title being recognized as problematic in many cases and separated from the custody and use of collections by museums. Numerous examples are already in place where museums manage and interpret collections by agreement with source countries or descendant communities rather than asserting title.

New Museum Formats

In an age of increasingly immersive and experiential entertainment, more didactic and static museums struggle to engage and retain visitors. Traditional forms of display tend to privilege authentic objects but struggle to place them into meaningful living contexts that excite the imagination of visitors. More interactive formats are better at creating a sense of wonder, but often do so at the expense of the real objects. The rise of virtual or online museums offers tantalizing promise for the provocative and multivocal interpretation of archaeological collections, yet it also poses significant pitfalls. Technical challenges are being addressed through innovative partnerships and increasing technological sophistication of museum staff, but some museum professionals see a risk of further undercutting support for archaeological collections by separating their public interpretation (which can be mounted without the infrastructural demands of brick-and mortar-museums) from their care and curation, which ultimately depend on physical space and staff.

North America (USA): Historical Archaeology

Lu Ann De Cunzo
Department of Anthropology, University of Delaware, Newark, DE, USA

Introduction

In the USA, historical archaeology involves cultural resource management, heritage studies, public and advocacy archaeology, and academic training and research. The National Archaeology Program comprises legislation, policies, education, funding, and land, site, and collections ownership and management in the public trust. A national register of historic landmarks and places and a system of national parks and monuments preserve an increasingly broad cross section of the nation's material legacy. These programs, along with an array of state, local, and private enterprises, enable people to confront material pasts. While archaeology remains implicated in the reproduction of mythic national histories in the USA, significant efforts to interrogate and challenge these histories strive to engender empathy and understanding of past struggles and experiences.

Multiscalar, multivocal approaches are most advocated, through which researchers consider individual objects or object constellations in local, regional, national, and global settings of production, exchange, consumption, use, and disposal. To understand people-object networks and entanglements, analyses are approached from the perspectives of individuals and groups in diverse structural positions in society. Contemporary historical archaeology in the USA is exploring how forces of colonialism, capitalism, nation-state formation, industrialization, mass population movements, racism, gender and sexuality, and cultural encounters shaped the post-Columbian world (e.g., Paynter 2000). This essay is structured around four issues that dominate our discourses and practices: the relationships of structure and agency, and of archaeologists and publics; the materiality of social and cultural processes and practices; and the global phenomena of colonialism, capitalism, and industrialization.

Definition

The definition, or boundaries, of historical archaeology has been contested from the beginning. Today, US historical archaeologists define the field as historical anthropological or anthropological historical approaches to study of (a) European colonial conquest and the encounters of peoples, environments, and objects that ensued; (b) capitalism and the modern world; (c) the past, using all available lines of evidence, including material culture (i.e., environment, landscape, architecture, objects, texts, images), living people, and memory.

Historical Background

The origins of the contemporary practice of US historical archaeology lie in (1) nineteenth-century anthropological archaeology studies of American Indian cultures, (2) Colonial Revival-inspired historic sites movement, and (3) Great Depression public works projects in the 1930s and 1940s. The nation's first heritage preservation legislation, the Antiquities Act, dating to 1906, established the federal government's responsibility to recognize and protect archaeological sites

on land it owns or controls. Historic sites like Virginia's colonial capital, Williamsburg, became the focus of private preservation projects in the 1920s and 1930s. Depression-era public works projects fostered the expansion in scope and scale of public archaeology across the USA and the development of salvage archaeology. Heritage and environmental movements in the 1960s led to legislation establishing the National Register of Historic Places, mandating national cultural resource inventories, and sponsoring surveys in advance of federal construction. These laws fueled the development of the cultural resource management industry in the 1970s.

Intellectually, historical archaeology has a dual, historically dichotomous, identity as science and/or humanity. This binary has opposed anthropological etic versus emic perspectives and foci on populations in environmental-cultural systems versus histories of peoples and their systems of meaning. Stanley South modeled the scientism of processual, New Archaeology for historical archaeology in his 1977 work, *Method and Theory in Historical Archaeology.* Processual archaeology challenged traditional "handmaiden to history" archaeology, seeking to reveal the material culture patterns defining site types and cultural affiliation, which in turn would elucidate processes of cultural variation and change. Studies of enculturation and adaptation in colonial settings ensued. James Deetz's *In Small Things Forgotten* also appeared in 1977, introducing a mentalist, structuralist approach to studying early American life. Deetz argued that the Enlightenment (Georgian) world view precipitated the greatest cultural transformation in European American life. This had implications for all material culture as people reordered their world in concert with their new understandings.

A related debate centered on sources of evidence, especially the place of documentary analysis in historical archaeology. Contextual, interpretive historical ethnographies of people and place and critical perspectives on the legacies of capitalism, racism, and nationalism began to appear in the mid-1980s. Their authors imagined the relationship of text, site, and object differently, but they shared a goal of critically querying and analyzing texts as well as traditional archaeological evidence.

Key Issues/Current Debates

Social theory, and especially debates over the relationship of structure (e.g., the state) and the nature, extent, and circumstances of individual agency, dominates the intellectual discourse in American historical archaeology today. Various theoretical perspectives orient research on social and cultural processes and identity along with global phenomena like colonialism, capitalism and modernity, industrialization and consumerism, and the institutionalization of American life.

Structure and Agency

Marxists rejected the social unity and ahistoricism of the concept of *world view* espoused by structuralists James Deetz and Henry Glassie. They take a dialectic view of the dynamic web of internal relations constituting society, giving special attention to the inherent contradictions of capitalism and the *ideologies* that reproduce it (McGuire 2006:125–127, in Hicks and Beaudry 2006). In this view, ideology defines the self-other relationships that structure people's understanding of the world (Burke 2006:137, 139 in Hall and Silliman 2006). For epistemological Marxists, ideology is true and false consciousness; the individual itself is an ideological construct of capitalism, as is the concept of agency itself in historical archaeology (Matthews 2010:2). Others hold a more sociological view, focusing on the function of ideology. They have adopted, and challenged, a variety of social theorists' conceptions, including Gramsci's hegemony, Althusser on ideology as material practice, Bourdieu's *habitus*, and Giddens' "lived experience" (Burke 2006:129–130, 133 in Hall and Silliman 2006).

Contextual, *interpretive* approaches seek to decenter master narratives and understand the multiplicities and ambiguities of past experiences. Attending to multilocality and multivocality, and reflecting on the relationships among archaeologists and their sources, these archaeologists produce alternative histories in the traditions of

historical ethnography, Clifford Geertzian "thick description," and narrative. They give voice to individuals and to everyday artifacts in innovative and provocative forms including artifactual storytelling and archaeological biography (Beaudry and Symonds 2010:xii–xx; Janowitz and Dallal 2013).

Feminist scholars argue for the centrality of gender in human history and have explored the construction and dismantling of gender hierarchies. They have replaced the either-or structuralist, androcentric perspectives inherent in previous archaeological research with inclusive both-and approaches in their studies of minorities as well as women (Spencer-Wood and Matthews 2011; Spencer-Wood 2013).

Historical ecological and *evolutionary* archaeologists are challenging another fundamental dualism: nature-culture. Work in the American West has conceptualized the environment as a networked ecological theater experiencing cycles of boom and bust prompted by global technological and economic change. Human action comprises strategic responses to this economy-environment in order to maximize profit opportunistically and resiliently, with the fittest surviving (Hardesty 2010). Insight into the intersections among contemporary environment-economy-public health problems is driving important work in this tradition, including contemporary garbology studies (Shackel 2009:3).

Social and Cultural Processes and Structures

Archaeologists continue to struggle with defining and operationalizing appropriate social analytical units for the study of self-fashioning and "othering." Scholars now challenge the family household as the basic social unit of analysis, charging that the choice represents an uncritical transferal of normative middle-class, European American domestic practices and ideals into archaeologists' methodological structures. Critically examining internal dynamics, production, and consumption activities, archaeologists seek to understand diversity and change within households and households' relationship to society (Fogle et al. 2015). Multiscalar identity demands multiscalar levels of analysis: individual personhood; meaningful, organizing social groupings; geographic proximity locally, regionally, nationally, and globally. Archaeological approaches to individual materiality seek to interrogate social identity and cultural diversity holistically through studies of embodiment, life course analysis, and networking. These analyses of intersectionality aim to reintegrate the individual and understand the interpenetrations of gender, race, sexuality, class, age, ethnicity, and other vectors of identity (White 2009; Janowitz and Dallal 2013). These structures are introduced below and elaborated in subsequent sections.

Gender and Sexuality: Current debates surround the biological sex-cultural gender model versus performance theory, which challenges the validity of the nature-culture duality (Voss 2006:107–108 in Hall and Silliman 2006). Gender and power studies highlight heterarchy and the diverse forms of power, with special emphasis on cooperative power. American historical archaeologists are latecomers to the study of sexuality and the application of queer theory and masculinity theory. Prostitution, birth control, reform institutions, and interracial unions have received most attention. Same-sex relations, sexual violence, and concubinage are more recent topics (Voss 2008).

Race: Racialization assigns people to essentialist groups based on physical appearance allowing them to be perceived as biologically inferior and socially unequal (Orser 2007:9). Many US archaeologists place racialization at the heart of American social life. Diasporas, the traumatic global movement of peoples involving famine, war, enslavement, ethnic cleansing, and conquest, create prime circumstances for racialization. Pragmatist philosophy contributes a focus on the consequences of actors' choices and actions (Agbe-Davies 2015); others are applying affect theory, queer theory, and ontological approaches to materiality (Arjona 2017, in White and Fennell). Another important impulse is the emerging generation of archaeologists bringing their lived experiences of racial dynamics to bear on their analytic perspectives (Fennell 2017).

Labor: Work involves material and social practices, not just technology, production, waste, and

products. The administration, management, supervision, and imposition of labor, as well as laborers' accommodations, resistance, and daily living, form growing foci of study.

Class: Although a considerable historical archaeological literature on class exists in the USA, the fundamental definition of class as a thing or a relation remains contested. In thing studies, class is imagined as a hierarchical ordering like a ladder. Marxian scholars see class as a dialectical relation comprising the whole of lived experience. They deconstruct experience to examine each part's fits and functions within the social totality (Wurst 2006:191, 195 in Hall and Silliman 2006).

National: Nationalist studies emerged in the context of American exceptionalism and explore the processes of becoming American. Fictive and illusive, national identity and citizenship (political and cultural) rely on practices of inclusion and exclusion that archaeologists can investigate at institutions of Americanization and through the politicization of consumption (Camp 2013). These archaeologies complicate our understanding of the interactions of power, language, history and tradition, religion, and perception that create, maintain, and subvert national identity (Brooks and Mehler 2017).

Ethnicity: US immigrant history has generated great interest not only in nationalism but also in the processes and purposes of ethnic stereotyping and boundary maintenance responses that challenge social marginalization. Current approaches focus on hybridity and the ways people imbue material culture with meanings that reference common identities. Heritage formation among ethnic groups is investigated as a process of constant reevaluation of these meanings based on new group experiences and structural changes (Brighton 2009:145–146; Fennell 2017).

Age: Age and life course studies in US historical archaeology are few. These are beginning to challenge essentialist perspectives on childhood and research children "becoming" and "being."

Religion: Processual scientism and Marxism in American historical archaeology have disparaged the importance of religion to past peoples and limited archaeological investigations of "mainstream" religion (Veit et al. 2009). Studies of Spanish missions and dissenting religious societies like the Shakers and Mormons, as well as gravestones and cemetery landscapes across the country, are countering this position. Renewed interest in the archaeology of religion, folk religion, magic, and ritual is dismantling Eurocentric definitions and the conceptual hierarchy of relationships (Manning 2014).

Global Phenomena

Colonialism

From the Atlantic World to the Pacific Rim, US historical archaeologists are probing how colonialism worked as a contentious yet "shared project" simultaneously in homelands and colonies. Long conceptualized as a neutral set of "contacts" among natives and newcomers, the shift to "colonialism" acknowledges the concerted effort of settler populations to dominate indigenous peoples based on ideologies of inherent inequality and racism, acts of labor control, dispossession, and economic marginalization (Silliman 2005:59–66). A "cottage industry of resistance studies in archaeology" has resulted; their challenge is to determine what constituted and meant resistance to whom (Liebmann and Murphy 2011:9).

Others counter that it is Eurocentric to cast all native actions in colonial settings as mitigating oppression. Doing so risks romanticization, homogenization, and a denial of agency. These archaeologists decenter resistance to examine other motivations and intentions (Liebmann 2011:200 in Liebmann and Murphy 2011). Some have turned to micronarratives to nuance and explain the generic macronarrative of the Columbian conquest (Liebmann and Murphy 2011:9–10). Rejecting essentialist notions of native material culture, they focus on processes of entanglement, survivance, ethnogenesis, creolization, hybridity, syncretism, materiality, social memory, and bricolage, actively repudiating concepts and narratives of tragedy, dominance, or victimization without necessarily assuming any group's cultural superiority (Kelly and Hardy 2011:181; Silliman 2005:68). Community and

persistence through residence are foregrounded, such as in recent work on Southern New England native peoples on reservations (Ferris 2009; Jordan 2014; Silliman 2014, in Ferris et al. 2014). Even more complex and informative about colonial processes of ethnogenesis and racism are examples such as the African Seminole emergence from alliances among Florida native people and African escapees from captivity (Weik 2012).

Environmental archaeologists are analyzing the interactions among native, settler, and environment that transformed pre-colonial landscapes. They are exploring the ways European livestock and crops impacted the environment as well as how colonists learned about the new environment, adjusted their practices and thinking, and ultimately relinquished their expectations from home as they sought to reproduce a familiar diet (Mrozowski 2006). Others are documenting the ways space served as a tool of racialization, resistance, and appropriation (Agbe-Davies 2015).

Informed by and challenging the Deetzian tradition, archaeologists continue to examine the implications of the Enlightenment in the eighteenth century. The nature-culture divide, order and chaos, reason and science, and the beginnings of individualism and consumerism represent central topics of concern (Matthews 2010:58–61). The culture of gentility that emerged within Atlantic world cosmopolitanism prompted growing consumerism in early eighteenth-century urban America from St. Augustine through Charleston, South Carolina, to New York, Boston, and Portsmouth. The commonality and variability among individual choices in personal hygiene, dress and adornment, and home furnishing and the elaboration of foodways have received special attention (Heath et al. 2017).

Capitalism and Modernity

Modernity is the central phenomenon of study for archaeologists who identify the USA as a nation-state founded on a culture of capitalism. However considerable disagreement surrounds the conception of modernity as a research orientation (Cobb in Heath et al. 2017:273). Some define capitalism as an economic system and social order for the creation of private profit. In capitalism, an ideology legitimizing consumer greed and accumulation enables the commodification of everything (Mrozowski 2006:11). For others, capitalism wrought a fundamental change in relations between workers and owners so that the former sell their labor to the latter. The key elements of US capitalism they examine include the factory system, time and body discipline, the corporation as a vehicle for capital investment, and the deskilling of labor (Shackel 2009:21–22). All share a critical interest in the construction of the individual in the commodity market, the sources of means to distinguish the self as an authentic individual (Matthews 2010; Leone and Knauf 2015).

Obstacles to archaeologists' ability to understand the material and discursive legacy of capitalism include inadequate conceptions of meanings of privilege, poverty, and wealth (Matthews 2010:44). For example, recent work is investigating African Americans' role in the market economy of the American South and the persistence of historical practices today (Joseph in Proebsting and Gary 2016).

Industrialization Historical archaeologists of nineteenth- and twentieth-century industrialization in the USA examine the technologies, costs and benefits, environmental impact, and laboring life-worlds associated with industrial processes of centralizing, mechanizing, and standardizing production. Technological studies address the machines, equipment, buildings, and landscapes that industrial labor created and altered and the raw materials and transformative processes that created consumer goods, tools, equipment, and transportation systems. Other projects are investigating the relationships, institutions, and practices that controlled workers' lives (Gadsby 2011:12, in Spencer-Wood and Matthews 2011). Archaeologists have documented the material growth, maturity, and evolution of industrial processes and the industrial city. Increasing privatization of workers, the growing importance of immigrant labor, and the erosion and ultimate abandonment of corporate paternalist responsibility for worker

welfare took material form in an increasing divergence in the living conditions and domestic environments of labor and management (Mrozowski 2006).

The industrialization of rural America through the development of scientific, mechanized agriculture forms another research focus. Archaeologists are probing the complex, uneven efforts to standardize and homogenize agricultural production in order to maximize efficiency and thus profit. In the twentieth century, rural electrification, new technologies and crop regimes, new class and gender roles and structures transformed rural life. Archaeological examinations of the material culture of domestic and farm life are revealing how people countered the pressure to homogenize locally, regionally, and socially (Groover 2008).

In the nineteenth and early twentieth century, scholars have argued that the American West was an "underdeveloped periphery of the northeastern, industrial, capitalist core" (Matthews 2010:132). Valued for its sites of resources extraction and low labor value, the West was dominated by corporate, regional hierarchies of resource extraction, milling, redistribution, and transportation. Workers in the West were predominantly unskilled, sharing similar experiences of transience and intense alienation (Matthews 2010:132–135). Archaeological work has centered on mining, the railroad, ethnic group experiences, and West Coast urbanization.

The USA has a long tradition of idealistic social reform. By the nineteenth century, many utopian or "intentional" communities had formed to reject or resist features of industrial capitalism and husband patriarchy. These communities, the Shakers among the most well known, used material culture explicitly to promote an alternative social order and relations. Recent research has emphasized the place of liminality and communitas in these projects and charted community responses to internal and external pressures over time. Feminist scholars are illuminating the interplay of ideology and practice in the construction of gendered hierarchies or equalities in these communities. All stress the importance of utopian imaginations today in creating a future not based on war, terrorism, and inequality (Kozakavich 2017).

Nature and Culture American historical archaeologists have increasingly accepted that the nature-culture dichotomy is a social construct. Under capitalism, abstract processes of commodification transformed nature into spatially and statistically differentiated units of exchange (e.g., land, animals, plants, water; Matthews 2010; Mrozowski 2006). In the Southwest, archaeologists are coming to understand "the subtle reorganization of the anthropogenic landscape resulting from the interaction and persistence" of indigenous, Spanish, and Anglo-Americans (Edwards and Trigg in Proebsting and Gary 2016). In colonial capitalist cities such as Boston, social and functional specialization and segregation led rather to dramatic anthropogenic changes to the environment (Landon et al. in Proebsting and Gary 2016). Deteriorating environmental conditions in mill and worker domestic yards produced poor sanitation, contaminated water, and high disease loads that city governments were slow to address (Matthews 2010:119–131; Shackel 2009:28–38). Later nineteenth- and early twentieth-century domestic reform movements also transformed urban landscapes, blurring the public-private and culture-nature ideological distinctions through creation of corporate housekeeping places and other alternative domestic forms (Spencer-Wood 2013).

Social Relations and Identity *Race*: For decades, archaeologists working at Southern plantations have investigated enslaved living conditions, foodways, belief systems, power relations, informal economies, and Africanisms and composed detailed portraits of life in bondage (Groover 2008). Today, African diaspora archaeologists are deconstructing whiteness and challenging racist histories and the persistence of racialization (Matthews 2010:178; Matthews and McGovern 2015). Informed by critical systematics, some are examining the implications and outcomes of object classification schema. Their

findings challenge essentialist categorizations that insidiously reproduce race and racism unsupported by the objects, which too often are invoked to stand in for people (Agbe-Davies 2015).

Black feminist archaeologists are illuminating the special exploitations associated with sexuality and enslaved women and the gendering of spirituality and African diaspora cosmology (Voss 2008:115). In the Northeast, the first region to enslave Africans in what became the USA and to craft postbellum multiracial societies, archaeologies of slavery and race are countering mythic narratives of the region as the home of liberty and abolition (Orser in Matthews and McGovern 2015).

Indigenous archaeology studies are contesting racist interpretations by rejecting static colonizer/colonized, Indian/European dichotomies and focusing on the constant negotiation of social categories. By engaging with indigenous categories and concepts, archaeologists deny European American intellectual superiority, diversify perspectives, and disrupt dominant, racist approaches (Ferris et al. 2014).

Concepts of diaspora and racialization have also been extended to explain the experience of other groups, especially the Irish and Chinese. One study of the Irish diaspora after the 1840s potato famine examined how Irish immigrants strategically used the symbols of their racialized identity to contest and disrupt the dominant discourse of exclusion and, ultimately, to accept the ideology of mainstream American consumerism and achieve a level of incorporation into American society (Brighton 2009). Studies in the Western USA examine the grounding of Chinese racialization in American isolationist anti-immigration policies and ideologies (Orser 2007:125–178; Voss and Allen 2008:5).

Class: The making of the middle class in nineteenth-century America, the segregation of work and home, shifting gender roles, domesticity and changes in household organization, and other entanglements have been explored in cities, towns, and farming communities from New York to California. Studies of the relationships between middle- and working-class cultures, for example, are rejecting the model of emulation, with its implications that working-class people lacked cultural autonomy (Mrozowski 2006:152). The recent economic downturn has revived interest in poverty, modeled as a form of internal colonialism. The capitalist ideology of individual responsibility for success and failure has effectively criminalized poverty (Spencer-Wood and Matthews 2011:1–2).

Consumerism and Domesticity Authenticity and competency in interpretive symbolic expressions became important in the ideologically individualistic society enabled by eighteenth-century mercantilism (Matthews 2010:3). Researchers are examining the processes of commodification, the capitalist networks through which commodities moved, and the impact of commodification on individual expression (Mullins 2011; Heath in Heath et al. 2017:56). Studies of nineteenth-century mass consumerism evidence technological advancement in foods, dining, hygiene, and health care reinforced by middle-class Protestant religious ideology that translated goods into social position and morality (Brighton 2009:123). In the industrializing West, large-scale producers and locals used consumption to adjust to transformations engendered by economies of scale, in the process creating new ways of life within capitalism (Matthews 2010:141–147). In the twentieth century, transportation and communication technologies spread goods and ideals into rural America, creating a national consumer culture (Paynter 2000:176).

Shopping studies have illuminated the active role of material culture at the moment of consumption, when value and meaning are assigned in these economic, social, and political acts of cultural recreation. At home, these new goods negotiated family and society, work and home, private and public, male and female, and women's moral authority and responsibility. In this way, mass production collapsed distinctions between the market and domestic sites like the dining

table, at which individualism and discipline were highly ritualized. But did hierarchies of dining wares, forms, styles, and functions sacralize capitalist social relations or the moral authority of women? Did lower middle-class, immigrant women in cities use expensive teawares to create community, reject isolation, express ethnicity, signal acceptance of capitalist ideologies, and/or assert domestic power (Brighton 2009:7; Matthews 2010:94–99, 158–159; Mullins 2011:178)?

The most stringent critique of archaeologies of consumerism claims that most archaeologists have yet to imagine approaches that challenge the simple presumption that past people were economically rational consumers who merely projected uncomplicated, bounded identities onto static material things (Mullins 2011:2–3). They do not ask why people *wanted* consumer goods rather than reiterating the factors enabling access such as availability, wage labor increases, social mobility, advertising, or simplistic explanations of emulation (Mullins 2011:2–3, 42–43). One current approach probes the reciprocal relationships between objects' social symbolic roles and the physical properties or materiality limiting or enabling those roles (Heath in Heath et al. 2017:3).

Violence

The archaeology of conflict and violence has a long history in US historical archaeology. Excavations at forts and battlefields have enabled study of ordinary soldiers and officers across time and space, the complexities of provisioning and transporting armies, the cultural landscapes of encampments, and the course of battle events using multiple lines of evidence (e.g., Comer 2013; Geier et al. 2014). Comparative analyses of forts are revealing differences in colonial nations' goals and approaches to dealing with the frontier, native populations and each other, as well as differences between expected and actual behavior that led to violent conflict (Cobb and Sapp in Geier et al. 2014). Other archaeologies of the American wars of independence focus on European cultural contributions to development of an American citizens' army, along with economic and political policies that precipitated and sustained war (Comer 2013.)

In the archaeology of nineteenth- and twentieth-century war, Civil War archaeologists marked the 150th anniversary of the conflict by launching initiatives to better understand enslaved and free African Americans' roles. At World War II Japanese incarceration camps, archaeologists are examining the camps' materiality as tools of racism and institutionalized efforts to break families, as well as the internees' responses.

Class war is another significant arena of violence archaeologists are targeting in efforts to historicize contemporary structures and promote social change. The mining industry is a special target, with projects in Colorado, Pennsylvania, and West Virginia (McGuire 2014). Archaeologies of sexual violence are emerging principally in the contexts of enslavement, colonial conquest, and prostitution.

Institutionalization of American Life

Archaeological studies of almshouses, schools, reformatories, hospitals, prisons, and asylums abound. The most provocative work asserts that America is a carceral society in which institutional confinement functions as a specific mode of population management. Asking "why incarcerate?" archaeologists probe the relation of individual and state and the ways that the state uses institutional incarceration to reconstruct the citizen-self and purge society of the uncivil and unproductive. Colonial institutions are situated in the context of European global imperialism (McAtackney and Palmer 2016). Archaeologists are examining the profoundly material, embodied experiences of confinement constituted in architecture, landscape, furnishings, tools and materials of labor, food, clothing and bodily care objects, and illicit objects. Study of these body-space-object relations reveals the dynamics of punishment, reform, and deterrence, domination and resistance, respite and ritual, survival and exchange in circumstances that deprive individuals of their basic security,

material possessions, social life, individual freedom, and personal expression (Casella 2007).

Archaeology and Publics: Community, Shared Authority

Archaeology is an act of commemoration, and archaeologists today are rethinking what, why, how, and for whom they are remembering. Recasting the relationships among archaeologists and publics has been driven by the ethical question of who owns the past, literally and figuratively. The issue of who makes decisions about preservation, access, commodity and intellectual ownership, possession, disposition, funding, and interpretation of archaeological sites, collections, and human remains in the USA is highly contested. Justifications for historical archaeology include learning, sharing, entertaining, provoking, empowering, promoting community and economic development, and undoing historical injustices.

Critical Marxists strive to gain knowledge of, critique, and transform the world (McGuire 2006:124, in Hicks and Beaudry 2006). They work to illuminate and intervene in power structures that deny freedoms. For example, historical archaeologies of urban gentrification and the active material erasure of the poor from the American landscape and economy reveal and challenge the process today (Gadsby 2011:22, in Spencer-Wood and Matthews 2011). Studies in this tradition advance a postcolonial present by defying those who use "notions of freedom and resistance to feed global domination and ideologies of privilege" (Weik 2012:153).

Critical scholarship also challenges the professional authority structures of bureaucratic archaeology in favor of local definitions of the value of the past and local archaeological action (Palus et al. 2006:84–100 in Hall and Silliman 2006). Community-centered projects are questioning the post-civil rights movement emphasis on positive change to reveal the constancy of racial inequality in the USA today (Matthews 2010:42–43). Others target labor struggles. Archaeological collaborations investigating the Colorado Coalfield War of 1914, in which the National Guard killed strikers and family members, galvanized unionized workers in the region today. They now see their contemporary struggles as a continuation of the struggle at Ludlow (McGuire 2014). This archaeological movement for working-class justice is gaining momentum, with projects such as the one at Blair Mountain, West Virginia, the site of another coal mine worker uprising in 1921.

Another impetus to reassess public archaeology in the cultural resource management sector is the current pro-development, anti-regulatory political climate in the USA. Efforts involve justifying how and why federal funds are spent, increasing program efficiency and knowledge of the past as well as public engagement, participation, and ownership (Sebastian and Lipe 2009; Matthews 2016).

Most Americans encounter archaeology as heritage tourists at museums and historic sites. These are key venues at which archaeologists help both to critique the white, elitist, progressive, and nationalist ideologies that have driven historic preservation and interpretation and to introduce more inclusive histories. Alternative, revisionist memories of negative heritage in the USA, for example, are being made at sites of military forts and battlefields, burial grounds, and institutions (Shackel 2009:95–103).

International Perspectives

Global historical archaeology is a rapidly expanding work in progress, engaging American archaeologists with alternative intellectual traditions, cultural processes, and phenomena, particularly in the Atlantic, Pacific, and Anglophone worlds. Reconsideration of scale has fostered explorations of the interconnections that have defined the modernizing world. A new holism is emerging, rooted in rejection of singular metanarratives and embracing of comparative perspectives. Archaeologists are probing and parsing local-global entanglements in diverse historical, geographical, social, and cultural contexts.

Many of these entanglements have colonial origins. American archaeologists are collaborating in new ways with indigenous peoples,

archaeologists, and publics in imperial homelands and other former New World, European, African, and Pacific colonies. Plant, animal, food system, pathogen, and manufacturing studies are deepening understandings of the biological and environmental exchanges and consequences of colonialism. Archaeologists are re-conceptualizing indigeneity in association with new models of hybridity, appropriation, resistance, adaptation, and identity and conducting in-depth, diachronic studies of diversity in European and local cultures, geographies, and sociopolitical organizations (Liebmann and Murphy 2011; Kelly and Hardy 2011). One important focus of this work is on the everyday lived experience of indigenous, marginalized, and colonized people (Ferris et al. 2014).

Increased attention to the colonial transformation of Europe since the fifteenth century is further complicating and challenging colonial metanarratives. So too is the explicitly global scope of diasporic orientations and the attention directed at the materiality of pre-diasporic experiences and structures and the forces leading to diaspora. Archaeologists are interrogating the materiality of alienation, accommodation, appropriation, acceptance, and other transformative processes experienced by diaspora subjects. In the process, they are problematizing and complicating concepts of resistance (Weik 2012).

Archaeologies of mobility trace the movement of goods, people, and ideas through time and around the world. "Through… engagement [s] with consumer goods, people in Asia, Europe, Africa, and the Americas created and maintained complex connections that influenced Western ideologies relating to individuality, community, and cosmology (Thomas 2004:5–6), and indigenous concepts of value, power, and spirituality" (Ogundiran 2002; Potter 2006; cited in Heath 2017). These changes were fundamental to the rise of modernity (Heath in Heath et al. 2017:4). So too were colonial institutions complicit in forging the materiality of modern power dynamics (McAtackney and Palmer 2016:472).

"Recent scholarship has revolutionized the ways in which archaeologists conceptualize capitalism and its effects…. New spatial geographies, time periods, and subjects have been opened up to the critical lenses of historical archaeology, highlighting the diversity of economic parts… across different contexts worldwide" (Leone and Knauf 2015:3). New perspectives on globalized industrial production challenge simple models that hold the global distribution of commodities responsible for threatening cultural diversity while revealing how a globalizing economy has bred environmental and social injustice. The scale and ubiquity of industrial facilities rendered obsolete by rapidly changing technologies and corporate quests for cheaper labor have produced an increasingly global trail of communities coming to terms with industrial legacies and identities. Similarly, the escalating destructive power of war technologies has scarred ever-larger areas of the global landscape, defying the imaginaries of victory and heroism that have inspired traditional memory-making and marking.

American historical archaeologists also share with international colleagues the current preoccupation with identity and identity-making processes and forces that characterizes the postmodern condition. Race and ethnicity, gender, sexuality, age, and other categorizations have been deployed in context specific, and often fluid, ways. Archaeologists show that identities are culturally constructed, not biologically determined (Leone and Knauf 2015:9; Ferris et al. 2014). Identity-making in the postmodern world has revived interest in heritage and cultural tourism. US historical archaeologists have found employment, opportunities for activism, and intellectual enrichment and challenges in the heritage industry (e.g., Schiffer 2017).

Future Directions

Pragmatic, economic, technological, legal, social, political, theoretical, cultural, and philosophical forces and events will inform the future of American historical archaeology, as they have the past. Economic recession and raging ideological

stalemates over America's capitalist-socialist future have shunted public attention away from archaeology. This has produced urgency in archaeology to confront the issues surrounding rights and privileges, public values, cultural memory, and shared authority. The outcome will have a profound impact on the future of the field. The relevance of historical material evidence to contemporary concerns will continue to justify future endeavors. Archaeologies of gender, sexuality, individuality, and consumerism will persist, with growing significance given to authenticity, advertising, and branding. With the aging of the post-World War II generation, the latter end of the life course promises to join childhood studies as a focus of interest. Archaeologists already study the recent past and the present, although not yet with full comprehension of how the lack of temporal distance is implicated in our preservation and interpretation decision-making. Indeed, historical archaeologists must prepare to engage with more complex temporalities in future studies of modernity and supermodernity.

American archaeologists must expand multiscalar, comparative approaches. More investigations of human-land-object forms of association, occupation, and ownership will illuminate alternative ways of valuing past material remains and guide decision-making for the future. "Studying history backwards" may help us understand the contested and contingent history of capitalism by elucidating the preconditions that shaped the present and considering how the present "conditions" the future (Wurst and Mrozowski 2014:211). Contemporary health, environmental, climatic, and social problems are transnational, and so must be archaeologists' contributions to their comprehension and solution.

The cultural resource management industry and academic historical archaeology must respond to both politico-economic challenges and the intellectual critique of historical archaeology as a capitalist practice and imperial force. Curricula designed to produce archaeological labor minimize anthropology and history, failing to prepare students to assess ideologies of progress, critique the contemporary global order, and counter the global heritage crisis (Gnecco and Dias 2015:689; Hutchings and LaSalle 2015:699, in Gnecco and Dias 2015).

All these future endeavors require historical archaeologists to reexamine the classificatory schemes used to organize and analyze artifacts, to negotiate rapidly changing technologies, and to make difficult decisions about curation. Social media, 3D animation, virtual reality, and other technologies must be used efficiently, innovatively, ethically, and with diligent attention to preserving data in accessible formats for the future. American archaeologists will continue to face a curation crisis. Digital curation offers opportunities but is no substitute for the materiality of the object. It remains crucial that archaeologists actively engage with diverse others about the question, what cultural materials from the past will have a future, why, and who shall decide?

North America During the European Contact Period

Michael Shakir Nassaney
Anthropology, Western Michigan University, Kalamazoo, MI, USA

State of Knowledge and Current Debates

Introduction

Beginning in the age of discovery and exploration, European powers made contact with Native peoples in North America and subsequently colonized the continent. The cultural encounters that took place in North America during the European contact period have had a profound influence on world history with a lasting material legacy. In conjunction with ethnologists, historians, and demographers, archaeologists have employed documentary sources, ethnographic materials, oral accounts, and pictorial images to decipher the archaeological traces of contact to understand the interactions between Natives and newcomers (e.g., Galloway 1991; Nassaney and Johnson 2000a; Paterson 2011: 133–196). Many of the central questions pertaining to the contact period revolve around the ways in which Indigenous peoples, Europeans, and Africans influenced each other and how they impacted the environment in the process of cultural interaction and colonial engagement. While earlier scholarship emphasized the dominating role of Europeans, more recent work examines the agency of colonial actors of various identities, their creative responses to a rapidly changing social and political landscape, and the benefits of such a shift in perspective.

This entry discusses the significance of the North American contact period within the context of a broader global historical archaeology. It begins by examining the spatial, temporal, and practical dimensions of the European contact period. A brief overview of Native North America at contact is presented, followed by a history of early exploration and colonial encounters. A discussion of archaeological investigations into the contact period and some of the interpretive frameworks that have been used provide the context for the framing questions and enduring themes that have guided and emerged from archaeological research. Some of the salient research results pertaining to the materiality of contact are presented along with current debates that will propel future work in fruitful directions as the field becomes increasingly inclusive and attentive to a multiplicity of voices that reflect various stakeholders with an interest in the outcome of archaeological studies.

The Spatial and Temporal Scope of the North American Contact Period

For the purposes of this entry, North America is defined in ethnological terms to include the continental area north of Mexico City. Early anthropologists differentiated the cultural and political attributes of the occupants of this large landmass from those of Mesoamerica – particularly the state-level societies of the Valley of Mexico, the Yucatan, and areas further south – and organized groups into culture areas based on cultural and material similarities and differences (Fig. 1). They recognized that Native North America was by no means uniform, since it was marked by considerable phenotypic variation representing more than 500 ethnic groups speaking nearly 300 languages organized into some 60 discrete linguistic families. Europeans lacked the conceptual framework to account for these populations when they first encountered them in the sixteenth century, leading to a range of divergent ideas

North America During the European Contact Period, Fig. 1 Culture areas of Native North America and the locations of select ethnic groups when first documented in written records. (Map drawn by Jason Glatz)

about their history and origins. Archaeologists have since demonstrated that North America has been occupied for over 10,000 years, while many Native groups claim ancestry on this continent since time immemorial.

A few archaeologists have proposed trans-Atlantic contacts in pre-Columbian times, some even dating back to the Upper Paleolithic. However, with the exception of limited Norse settlement in the north Atlantic, no contacts prior to CE 1492 have been substantiated archaeologically. Thus, the contact period in North America began in the late fifteenth century and "by convention... commonly refers to the temporal range in which European colonists and Native peoples established social relations" (Wilcox 2009: 27). Of course, Indigenous communities interacted with culturally diverse peoples prior to the arrival of Europeans. Moreover, because contact can take many forms, it is incumbent upon scholars to define what they mean precisely by "contact" and to justify its analytical utility.

Bradley (2012) has suggested four phases or stages in the contact experience. The first phase is a rumor or report of an unusual occurrence. The second phase is marked by physical evidence such as a piece of imported brass or a glass bead. In the next phase, initial face-to-face contact occurs, and this becomes sustained interaction in the fourth phase. These phases may occur very rapidly or over a period of decades in some regions.

The first two phases have been referred to as "protohistory" to describe the indirect impact of Europeans (Paterson 2011: 167). This connotes derisively that Natives lived "before history" until Europeans arrived, a distinction reified by the term "prehistory." While the terms prehistory and protohistory are fading from use in many scholarly circles due to their pejorative connotations, documentary sources undeniably were created and are available for study in some cultural

contexts (when literate people were present) and not in others. Rather than seeing documents as creating a gulf between periods, they can be viewed more profitably as another line of evidence for historical reconstruction. Of course, written documents are no panacea for historical archaeologists and must be used critically just as should all sources since they harbor biases and limitations (see Galloway 1991).

Some archaeologists have critiqued the contact period terminology and the conceptual baggage associated with it (Silliman 2005), preferring the term "colonialism" because contact implies a benign relationship of relatively short duration. On the other hand, colonies as an extension of empire did not exist for much of North America until the last half of the seventeenth century when both the French and the English became real imperial powers. Before that, most of the European settlements in eastern North America were commercially based enterprises or religious refuges. The advent of colonialism involved "the projects and practices of control marshaled in interactions between societies linked in asymmetrical relations of power, and the processes of social and cultural transformation resulting from those practices" (Dietler 2005: 54). Contact in North America consistently carries colonialist connotations.

Colonies, by their very nature, are associated with states and empires during periods of expansion (Rogers 2005: 353). Colonial ventures provide opportunities for trade, information exchange, technological transfer, and ethnogenesis – the creation of new ethnic groups and forms of cultural practice. From an archaeological perspective, colonialist relations often involved goods that were produced, exchanged, and employed to further the colonial enterprise or resist its imposition, along with the ideological changes and continuities that accompanied it. Given its focus on the long-term and the material conditions of social life, archaeology is well poised to contribute to our understanding of cultural contact and entanglement. By examining the expansion of the capitalist world system – which was responsible for the most extensive implementation of colonialism (and contact) in world history – archaeology can expose evidence that is complementary and sometimes contradictory to written documents (Nassaney and Johnson 2000b; Dietler 2005: 50). The archaeology of contact is firmly grounded in the field of historical archaeology, which emerged in North America in the 1960s as the study of the expansion and impact of European culture. While material culture in all its forms is central to the field, historical archaeologists typically employ multiple lines of evidence produced in different contexts to interrogate and interpret how artifacts and the built environment were implicated in the interactions engendered by contact in North America.

Native North Americans on the Eve of European Contact

Prior to European explorations, mobile hunter-gatherers, semisedentary horticultural societies, and more centralized agricultural groups occupied most of North America north of the Rio Grande. Farmers dependent upon maize, beans, and squash were concentrated in the Eastern Woodlands and in arable areas of the Southwest (Fig. 1), whereas others could rely on the natural bounty of the environment that yielded plentiful plant and animal food resources that varied by season and locale. Some groups modified the landscape to increase resource productivity through the construction of raised fields, irrigation ditches, fish weirs, and wing traps to capture animals. Many also managed resources through controlled burning that encouraged edge areas and promoted other ecological benefits. Native peoples everywhere scheduled their activities and movements in accordance with the spatial and temporal distribution of resources and devised social networks to buffer against resource fluctuations. Reciprocity was widely practiced as the means by which goods were distributed and consumed.

Kinship was the dominant metaphor in Native societies and created a sense of belonging by virtue of the roles that were assigned to individuals according to age, gender, and skill. Women were generally seen as life givers and in charge of reproduction, plant gathering, cultivation, and child rearing. Men, in contrast, played a more public role spending much of their "time away

from their villages and families, hunting, trapping, fighting, and conducting diplomacy" (Kicza and Horn 2013: 22).

Political positions ranged from achieved to hereditary in different ethnic groups. Power was seldom monopolized as leaders were expected to lead through example and consensus was usually sought. While men held many of the political offices in Native societies, women were not excluded. They could also exert influence both directly through the leaders they selected for office and indirectly through gossip and other informal means. In general, male and female roles were seen as complementary in Native societies without one having dominion over the other (cf. European patriarchy).

Native cosmology recognized various animated forces at work in the universe, both in this world and in the upper and underworlds. Phenomena and objects as diverse as trees, the wind, illness, stone tools, animals, and celestial bodies were seen to have inherent qualities that were to be respected as part of an interdependent web of connections that were important to sustaining human life. Ritual acts were often oriented toward maintaining those interconnections so as to achieve and renew the physical, social, and ideological well-being of individuals but more importantly, the community. This is the worldview that guided many Native peoples as they tried to rationalize and accommodate the European invasion.

Early European Explorations and Encounters in North America

Europe was marked by an expanding mercantile economy in the fifteenth century with the capital and infrastructure to seek out raw materials and luxury goods in distant lands. Early encounters with Native peoples were initially unintentional and incidental; Native groups were not initially part of Europeans' imperial designs, though they were subject to immediate manipulation to ensure a competitive advantage in territorial expansion. While the history of encounters and appropriation varies in its details, what followed for several centuries throughout North America are a recurrent series of social, political, economic, and ideological contests that pitted Native against newcomer in a struggle for power and hegemony. Abductions, disease, warfare, exchange, intermarriage, migration, conversion, overexploitation, accommodation, and rebellion occurred repeatedly on a pan-continental scale as a result of cultural interactions involving misunderstanding, fear, greed, and power.

In the early years of contact, European settlement was often tentative and ephemeral. Natives usually outnumbered Europeans who depended upon their hosts for subsistence, marriage partners, appropriate technologies, and information needed for survival. To court their favor, Europeans often presented Natives with gifts such as cloth, glass beads, brass bells, copper kettles, iron hatchets, knives, axes and other metal implements, which they employed in familiar and innovative ways (Loren 2008). Failure to live up to Native protocols in exchange and other interactions was often disastrous, leading to conflict and ruin (Mallios 2006). Eventually, European disease, warfare, and subversive political tactics weakened Native groups allowing Europeans to gain a foothold. But not before Native groups made concerted, collective efforts to repel Europeans and restore former cultural practices. Rebellions and revitalization movements, such as King Philip's War (1675–6), the Pueblo Revolt (1680), the Natchez Uprising (1729), and Pontiac's Rebellion (1763), were common events throughout the history of contact. European imperial desires could be thwarted by Native actions indicating that outcomes of contact were always contentious, often negotiable, sometimes amicable, and never inevitable. This is easily forgotten when the history is told from the perspective of the dominant culture that assumed Native disappearance, marginalization, or absorption instead of continuity, persistence, and survivance. This divergence of perspective fuels the politicization of the contact period and leads to significant disagreements over reconstructions of the past. The causes and effects of European and Native actions are of central importance to our understanding of the contact period and are constantly being reinterpreted in light of new theoretical frameworks that illuminate data from varying angles, a recurrent theme of this essay.

North America During the European Contact Period, Fig. 2 Routes of European explorers, territorial claims of European powers, and locations of early colonial settlements and archaeological sites. (Map drawn by Jason Glatz)

N

In the sixteenth and seventeenth centuries, the Spanish, French, Dutch, and English vied openly against each other in North America (Fig. 2). Expansion was driven by efforts to discover a westward passage, find new tribes to convert, search for resources, and stake territorial claims. Explorations across the north Atlantic were undertaken to exploit rich sources of codfish or seek a more direct route to the Far East, which gradually led to increasing geographic knowledge of the North American landmass. Capitalizing on developments in seafaring technologies, England, France, and Spain became the dominant colonial powers as they claimed territory and established permanent settlements in North America. The shifting political geography of North America reflects the ebb and flow in the fortunes of various empires as they attempted to control land and exploit profitable commodities to bolster national pride and fill royal coffers.

By the middle of the eighteenth century, England had permanent settlements along the Eastern Seaboard from the Gulf of Maine to the South Atlantic Slope with a combined population in excess of one million colonists (Fig. 2). English posts also ringed Hudson's Bay to take advantage of prime northern fur-bearing animals. France had entered the interior of the continent through the St. Lawrence River valley and expanded west into the Great Lakes region, nearly to the Rocky Mountains, and down the Mississippi River Valley to the Gulf of Mexico. Spain had settled the southern reaches of the continent, following on the early explorations of de Soto in the Southeast (1539) and Coronado in the Southwest (1540). They eventually blended missionary and agricultural activities to harvest souls and cash crops through the use of Native labor.

The Spanish first landed in Florida in 1513, though their efforts to colonize the Southeast were largely unsuccessful. The de Soto *Entrada*

(1539–1543) traveled hundreds of miles through the region and eventually crossed the Mississippi River. Its chroniclers have left us tantalizing glimpses into chiefly societies before their dissolution. Apart from the presence of a limited number of Spanish goods in Native sites, the most lasting effects of the *Entrada* were the trail of destruction left in its wake and the deleterious effect that disease may have had among the population. Spanish settlement, beginning with the establishment of St. Augustine (1565), was confined to Florida. Towns, fortifications, and missions soon dotted the landscape until the late eighteenth century when Spain ceded Florida to the English.

Spanish settlement of the American Southwest followed from the successful conquest of the Aztecs further south in the sixteenth century. Northern Mexico contained some of the richest silver deposits in the region, prompting the Spanish to found mining towns and establish farms and ranches to feed these communities (Kicza and Horn 2013: 121). The Spanish also established missions on the frontiers of their empire in Texas, Arizona, and eventually Alta California (1769) as they had in La Florida. Efforts to expand north were in response to Russian exploitation along the Pacific Coast and England's territorial acquisitions after the Treaty of Paris (1763), which posed threats to the security of Spanish colonies. The Franciscans attracted Natives to their missions and attempted to convert them to agriculturalists and Christianity. The surplus produced in the missions supplied the nearby *presidios* (military bases) where soldiers were stationed for protection and to help capture runaways, demonstrate Spain's claim to California, and block Russian expansion to the south.

In the course of exploring and colonizing the continent in their search for precious metals, spices, and a route to the Far East, Europeans often settled for less lucrative resources like fish, timber, and furs, particularly in more northerly regions. Native peoples were usually recruited to harvest the raw materials, which were acquired through trade for manufactured goods. Exchange was one of the most significant mechanisms of interaction during the contact period, serving social, political, as well as economic functions. The depletion of furs in Europe enticed Basque and French fishermen to exchange iron and brass trifles for furs in Newfoundland perhaps as early as the fifteenth century. The demand for furs and hides fueled the trade, which became pervasive throughout North America and persisted for nearly four centuries. The fur trade illustrates the types of relationships that developed between Natives and Europeans and their social, economic, political, and environmental effects.

The French were especially active in the fur trade beginning in 1534 when Jacques Cartier encountered Micmac Indians near the mouth of the St. Lawrence River willing to trade furs for European goods. The English and Dutch soon entered the fray, exploring and subsequently establishing settlements along Hudson's Bay (1608) and the Hudson River (1614), respectively – bodies of water that provided access to the resources of the continent's interior. The English, Dutch, and French soon realized that furs were plentiful and potentially profitable. Competition to obtain the furs from Native producers in North America drove political and economic relations well into the nineteenth century.

Beaver was the preferred fur-bearing animal in much of North America, predominantly for its short undercoat fur that could be processed into felt for hats that marked social status in Western Europe and in the colonies. But other animals were also deemed desirable for various purposes leading to trades in buffalo, sea otter, and deer. Furs were implicated throughout North America during the contact period. Whatever the specific resource, European traders generally relied on Native peoples to capture and process the furs, for which they obtained manufactured, imported goods that served to cement the relationships that were more than merely economic in nature.

While the fur trade illustrates the close entanglements between Europeans and Natives, it also drove exploration as beaver were overexploited and sources of furs began to decrease along the Eastern Seaboard. After 1700, Native peoples in the northern fur trade no longer brought their furs to large trade fairs in Montreal; the French began

expanding west and establishing trading posts in closer proximity to their Native allies. French exploration and expansion of the trade was made possible by support from the Crown, knowledge of the interior gained from the Natives, and a desire to claim new lands in advance of other Europeans.

For the French, who were never able to attract as large of a settler population as the English or Spanish, Native relations in the fur trade were essential for their survival in the New World. The fur trade was the glue that bound the interests of the French and their Native allies against their enemies – the English and the Five Nations Iroquois. It also demonstrates that alliances were not always built along cultural lines. In an effort to secure the interior, establish Native alliances, and thwart British and Iroquois efforts to expand westward from the Atlantic Coast, the French established a string of posts in the western Great Lakes region beginning in the late seventeenth century (Fig. 2). Among them was Fort St. Joseph, an important frontier outpost in the North American interior (Nassaney et al. 2003). Initially established in the 1680s as a mission on the St. Joseph River near a strategic portage that linked the river and the Great Lakes basin to the Mississippi drainage, the fort became the keystone of French control of the southern Lake Michigan region. For nearly a century, this post served as a hub of commercial, military, and religious activity for local Native American populations and European colonial powers. It afforded a vital link in the colony's communications network and played a major role in the exchange of manufactured commodities for furs obtained by the Natives.

While the French controlled much of the trade in the St. Lawrence-Great Lakes riverine system, the English had established settlements in Massachusetts and Virginia. From Jamestown (1607), they hoped to raid Spanish vessels returning to Europe laden with precious metals. The region soon supported a considerable population that profited from tobacco production. The Pilgrim settlement at Plymouth (1620) was founded for religious freedom in an area that had been decimated by disease. The remnant peoples there welcomed the English as potential political and military allies against the Narragansetts who had been less affected by the epidemics (Kicza and Horn 2013: 153–154). The English population, which grew rapidly with settlements at Boston (1630), Springfield (1636), Providence (1636), and Hartford (1638), soon placed pressure on Native lands in the region. An early effort to confine Native groups to small tracks of land occurred in eastern Massachusetts beginning in the 1650s where John Eliot established a series of "praying towns" that were ostensibly designed to convert Native peoples to Christianity and assimilate them to English society, albeit with marginal success.

The Narragansetts and neighboring coastal groups in southern New England played important roles in colonial politics throughout the seventeenth century. These people participated in the fur trade by producing wampum – beads from marine shell – that were exchanged to the colonists for manufactured goods (Bradley 2011) (Fig. 3). The wampum was in turn moved into the interior where it was accepted in trade for furs. Through networks like this, European goods reached Native hands long before Indigenous peoples saw the traders themselves.

North America During the European Contact Period, Fig. 3 Wampum has been referred to as the magnet that drew the beaver out of the interior forests. Made of marine shell from coastal New England and New York, these small, cylindrical beads served political, social, and economic functions throughout the colonial period in much of the Eastern Woodlands. Length: 70 mm. (Photo by Lisa Marie Malischke)

The English also sought to access furs from the interior through a more northerly route; hence, they chartered the Hudson's Bay Company (HBC) in 1670 and established several posts along the shore of the bay to keep down costs (Klimko 2004: 160–161). As with the Montreal trade fairs, aboriginal groups were drawn to the HBC posts to trade. Also similar to the French situation, the presence of independent traders who traveled into the interior eventually forced the HBC to construct inland posts, prompting western expansion (Klimko 2004: 161) stretching all the way to what would become British Columbia and US Pacific Northwest.

In an effort to anchor Britain's claims to the Oregon Country, the HBC established the headquarters of its Columbia Department at Fort Vancouver in 1825 (Wilson 2011: 7). Over the next two decades, the fort became the fur trade capital of the Pacific Northwest with warehouses, locally produced goods, and agricultural surpluses to supply fur brigades, Indians, settlers, and up to two dozen other company posts in the department "from Russian Alaska to Mexican California and from the Rocky Mountains to the Pacific Ocean, a territory of approximately 700,000 square miles" (Wilson 2011: 7). Peoples of diverse backgrounds inhabited Fort Vancouver including English, Scots, French-Canadian, Hawaiian, Portuguese, *métis*, or from one of more than 30 Native American groups including Cree, Delaware, Haida, and Iroquois. The offspring of European fur traders and Native women led to the creation of a distinctive *métis* identity (Wilson 2011: 10). Some colonial powers such as Spain, Russia, and France encouraged interethnic unions as a strategy to populate distant frontiers (Lightfoot 2005: 216). While Britain did not, it was often difficult to regulate practices at places distant from the metropolis.

A rigid social hierarchy marked colonial life throughout much of North America. Moreover, this hierarchy was expressed through distinctive consumption patterns associated with food remains, ceramics, architecture, and a host of other prosaic objects used and discarded in daily practice. In the Columbia District of the Northwest, clerks and officers occupied buildings within Fort Vancouver's palisade, whereas *engagés* (company employees) lived in a multiethnic village of over 600 people. The higher ranks were generally English, Scottish, or French-Canadian, whereas the hired hands were French-Canadian, American Indian, Hawaiian, or *métis*. Cultural background dictated to a large degree one's occupation and prospects for economic mobility (Langford 2011: 30). In addition to processing furs, activities included logging, ship building, farming, and various crafts to support and diversify the economic pursuits of the company (Wilson 2011: 8–10). The artifacts recovered from the site testify to this social variation as well as the cultural changes that were taking place in house construction, subsistence, and dining practices and the accommodations the villagers made to intense cultural interactions.

Europeans made contact with coastal peoples of the Pacific Northwest well before the HBC. Sir Francis Drake had visited the region in the sixteenth century, but the English did not establish any permanent settlements there. However, after the Russians began to acquire and market pelts to the Chinese in the seventeenth century, they soon crossed the Bering Strait (1742) and settled in Alaska to exploit sea mammals for their furs (Lightfoot 2005). From 1743 to 1800, Russian fur traders obtained more than eight million rubles worth of skins (Gibson 1988: 376). In 1799, Tsar Paul granted the Russian-American Company a charter giving it a monopoly over all Russian economic activities in North America. Employing Hawaiians, Aleuts, Native Californians, and Creoles (offspring of Russian and Native unions), the Russians instituted a system of forced labor to acquire furs from Alaskan waters and as far south as northern California that could be sold at a considerable profit to Chinese merchants. Russian exploration along the California coast led to the establishment in 1812 of Colony Ross at the mouth of the Russian River just north of San Francisco Bay. The purpose of the settlement was to grow wheat and other crops to sustain Russian traders in Alaska, hunt marine mammals, and trade with Spanish California (Lightfoot 2005). The site was a successfully functioning multicultural settlement for nearly 30 years when the

Russian-American company decided to abandon the colony due in part to the depletion of the California sea otter population. Mexican and American settlers also posed a challenge to Russian claims in the region, demonstrating that sovereignty in North America rested on the ability to seize, occupy, and hold territory – usually by force.

This brief overview suggests that there was significant temporal, spatial, and cultural variation in the activities associated with Native and European interactions in the contact period of North America. Yet similarities abound as all areas experienced trade, information exchange, technological innovation, and the creation of new forms of cultural practice (Rogers 2005: 352–3). Archaeology can provide the data to examine how these large-scale processes were experienced at the local level since archaeological materials derive from daily activities. Approaches to the archaeological record of contact have changed over the past century in accordance with intellectual shifts both internal and external to the discipline and form the basis for the following discussion.

History of Archaeological Investigations into the Contact Period

Anthropologists showed little interest in the contact period and its consequences in the early twentieth century. Driven by the salvage ethnography that aimed to capture traditional Native culture prior to contact, ethnographers such as Franz Boas, Alfred Kroeber, Robert Lowie, and Julian Steward aimed to reconstruct Native societies unspoiled by European influence (Ramenofsky 1991). The prevailing ideology of the dominant society posited the vanishing Indian; assimilation was seen as the means for Native survival, as promulgated in government policies such as the Dawes Act of 1887, which sought to complete the process of dispossessing Natives from their land. With the advent of acculturation studies in the 1930s and the work of the Indian Lands Claim Commission (1940s), archaeologists began to examine the impact of European culture on Native societies. They aimed to demonstrate the ways in which Native societies had become more like European ones, perhaps most readily apparent by the imported goods that they had adopted. The advent of processual archaeology in the 1960s, which sought generalized and dehistoricized explanations for human behavior, did little to promote contact period studies (Wilcox 2009: 46–48), nor did the rise of historical archaeology that focused on European sites of national significance like Williamsburg, Mount Vernon, and Monticello, though trading posts were also of interest (e.g., Fort Michilimackinac). Most of the posts were examined for purposes of reconstruction with the aim of interpreting their role in manifest destiny and in support of other national myths (see Klimko 2004).

The Native American Reorganization Act of 1934, Native activism such as the formation of the American Indian Movement in the 1960s, increasing numbers and vocalization of federally recognized groups, and the debates that led to the Native American Graves Protection and Repatriation Act (1990) laid the groundwork for the conceptual spaces needed to discuss Native history, the contact period, and colonialism in fundamentally different ways by the late twentieth century. Despite claims to the contrary, Native living descendants had not vanished. Many were hidden in plain sight, and their cultural persistence, as expressed in practices and beliefs that set Indigenous peoples apart from the dominant society, contradicted the dominant narrative and the biological imaginings that justified dispossession. Under the banner of post-processual archaeology, interpretations shifted toward an interest in meaning, an insider's perspective, and multivocality. While it is difficult to tease out the influence of Native voices from the contributions of other disenfranchised groups (e.g., people of color, other minorities, and women) to this movement, what is clear is that political action effected this change (Nassaney 2012). As a result, Indigenous peoples and other stakeholders throughout the United States and in many other parts of the world are now seen to have a legitimate interest in the past and, by extension, a concern for archaeology. More specifically, the interpretations given to the events of the contact period have practical implications. Furthermore, Native experiences in

the contact period were different from those of the colonizers. This realization underscores the idea that archaeological interpretations can serve, reinforce, or challenge dominant *and* subordinate ideologies. These pragmatic concerns over power inform the interpretive frameworks that have been used to examine the contact period, a summary of which follows.

Interpretive Frameworks

Whatever happened in the European contact period remains unchanged; however, our perceptions of it are constantly in flux due to shifts in the way we see the world based on our theoretical framework, social identity, and a host of other factors (Nassaney 2012). A number of interpretive frameworks have been employed to examine the contact period. They are presented in roughly chronological order, but they should not be seen as paradigmatic replacements. Some approaches are complimentary, while others are clearly contradictory and developed in response to shortcomings of previous perspectives.

Acculturation was the dominant interpretive framework for understanding the contact period for most of the twentieth century. Acculturation often carried the embedded assumption that European culture was destined to replace Native cultures due to racial and technological superiority. This explained the drastic and continued decrease in Native population and the proclivity of the survivors to adopt European goods. Researchers employed this relatively straightforward – though in hindsight theoretically unsophisticated – research methodology by comparing quantities of traditional and imported objects to assess the extent to which Indians had become civilized. The increase in Western goods over time was interpreted as evidence for the inevitable process of cultural decay.

The rediscovery of Marxian approaches in anthropology in the work of Eric Wolf and others in the 1950s paved the way for a concern with political economy and the ways in which labor is organized and surplus is mobilized on a global scale. World-system theory sought to explain the factors that led to global inequities and identified core areas of resource accumulation and peripheral areas of resource extraction. Gold and silver mines in Spanish possessions, English plantations run by African slave labor, the French fur trade, and other New World practices were the means by which Europe underdeveloped and economically marginalized their colonial subjects. While world systems explained the growth of mercantile capitalism, it failed to account for the diversity of responses at the periphery and denied the disenfranchised proletariat the exercise of agency in their actions and avenues for self-expression, accommodation, and resistance.

Critical theory is another organizing framework that owes its genesis to Marx and his predecessors and has played a role in contact studies (Nassaney 1989, 2012). Critical theorists posit that contemporary social and political conditions influence interpretations of the archaeological record that, while created in the past, only exists in the present. Thus, material remains are subject to varying interpretations according to the personal and political predilections of the interpreter. Critical theory calls us to recognize that the archaeological record is underdetermined with ample room for ideological bias to creep in.

It follows that seemingly disempowered stakeholders in excluded positions can use archaeology to challenge the status quo and subvert a dominant ideology. In the post-NAGPRA world, an Indigenous archaeology has emerged that aims to reintegrate "Indigenous materials, remains, history, and research with contemporary Indigenous peoples" and their concerns (Wilcox 2009: xii). By creating conceptual space for Indigenous matters, the narratives that posit the disappearance and alienation of Native peoples from their pasts can be reversed, and attention can be focused on explaining the rather remarkable existence of Native peoples in contemporary society 500 years after Columbus (Wilcox 2009). The archaeologies that result from such practice and our understandings of the contact period will be fundamentally transformed.

While yet to be fully realized, some archaeologists are attempting a comparative study of colonialism through which the experiences of all people within the contact period in North America and beyond can be juxtaposed to gain an

understanding of "glocalization" – the intersection between the global processes that accompanied contact everywhere and the local responses of colonial subjects (both colonized and colonizers). Moreover, the genres have become blurred, to paraphrase Clifford Geertz, in a process of hybridization that challenges us to avoid essentialized categories like dominant/subordinate, colonized/colonizer, and continuity/change. These identities are increasingly seen as fluid and situational and can be no more fixed in matters of policy than in material practices. The archaeology of the contact period, with its theoretical ebbs and flows, gives us an opportunity to create a new world in the twenty-first century as we simultaneously rewrite the past by interpreting material remains in ways that accord with a larger chorus of voices that strives for justice and equity. Ultimately, the archaeological study of the contact period can shed light on cultural continuities and discontinuities as two sides of the same coin and its significance for understanding ourselves in the present.

Framing Questions and Enduring Themes in the Archaeology of European Contact

Just as our understanding of the contact period is in flux, so too are the framing questions that we pose about the past. Yet in an effort to situate knowledge claims, culture contact archaeologists want to know what we know about past culture contact and how we know it. They aim to determine the types of encounters that occurred and their outcomes. Moreover, they are particularly interested in the material manifestations of the human responses to culture contact.

Murray (2004) has identified five variables of interest in the archaeological study of contact in settler societies, which were developed to examine contact in a comparative framework. These include (1) chronology of colonization, (2) types of societies encountered, (3) intentions of the colonizers and responses of the colonized, (4) demographics of colonization, and (5) duration of colonization (see also Lightfoot (2005) and Rogers (2005) for complementary organizing frameworks). Although these categories are by no means mutually exclusive, they can serve to focus the study of the archaeological evidence in the contact period in select areas of North America in an effort to highlight enduring themes.

Basic archaeological matters of space, time, and form interest archaeologists who study culture contact, even though they have access to documentary sources. Researchers continuously work to establish a chronological framework for contact by creating artifact typologies that are temporally sensitive (e.g., Quimby 1966). In the Southeast, archaeologists have tried to identify and locate objects associated with de Soto in order to trace his travels through the region. More importantly, such objects can increase temporal precision of sites in order to examine their distribution over time to evaluate models that posit shifting political and population dynamics prior to European contact. Chronology is an important variable because the changing political and demographic conditions of both Indigenous societies and colonizing powers influenced the type and intensity of impact. For example, the strategy and tactics that Native peoples used to counter English colonialism in southeastern New England changed considerably after their experiences in the Pequot (1637) and King Philip's (1675) wars; thereafter, they employed new strategies of accommodation to ensure biological survival that influenced settlement-subsistence strategies and land use practices.

The nature of social formations had a significant impact on the activities and outcomes of colonial interactions. Groups ranged along a spectrum from relatively egalitarian, hunter-gatherers to more centralized, ranked societies. These organizational forms often correlated with population size and surplus mobilization. As European populations increased, Native mobility was compromised making it difficult to maintain traditional subsistence practices. The result was often a decrease in mobility, more intensive land use practices, or wage labor that required new seasonal movements.

The effect of contact on Native peoples has been a central issue in the study of culture contact. Research shows that there was considerable variation in the "degree to which colonial agents actually dominated native peoples and exerted

power in the exploitation of resources, goods, and labor" (Lightfoot 2005: 210). In order to assess this process in qualitative and quantitative ways, archaeologists often sought to establish an ethnographic baseline. Thus, considerable efforts have been expended on identifying the precontact predecessors of historically documented ethnic groups often using the direct historical approach. Archaeologists have also challenged the reliability of the ethnographic record, arguing that groups were compromised by disease and population loss and consequently were fundamentally transformed by the time their lifeways were documented (Ramenofsky 1987). While most archaeologists agree that Native societies had no immunity to Old World diseases before contact, there is little consensus on the severity of population loss. Precontact population estimates range from 1 to 18 million (see Ramenofsky 1987: 6–21). While a reliable estimate likely falls somewhere in between, it seems equally likely that catastrophic disease often led to population decline well in advance of permanent European settlement in some parts of North America such as the Lower Mississippi Valley. Those groups that were located farther inland, those that were mobile, or those that were necessary for European survival were likely to have had different post-contact experiences (Ramenofsky 1987: 175).

Permanent European settlements along the Eastern Seaboard in the seventeenth and eighteenth centuries led to large-scale population shifts from east to west over much of the Eastern Woodlands. Such movements in turn pressured adjacent groups in a domino effect that had significant consequences for group size and ethnic identity. For example, the Five Nations Iroquois experienced population decline in the early seventeenth century perhaps brought about by European disease. They used guns acquired from the Dutch to exert military pressure on neighboring tribes to obtain war captives that could be adopted as fictive kin. This aggression triggered a series of population movements that led to demographic shifts felt onto the Plains. Southwest Michigan was abandoned, and the Potawatomis migrated to the western shore of Lake Michigan where they coalesced with unrelated groups. Amalgamation was partly a result of demographic imbalances brought about by disease and warfare, factors that were critical in the changing social landscape of Native North America after contact.

In southwest Michigan, archaeologists are examining the distribution of settlements immediately before, during, and after the French and English occupancy of Fort St. Joseph. Precontact settlements seem to lack imported manufactured goods, which typically were available well in advance of permanent European settlement (cf. Ehrhardt 2005). The absence of sites that reflect the "protohistoric period" suggests that the region may have been abandoned in the mid-seventeenth century due to Iroquoian threats; reoccupation followed after the French pacified the area in the late seventeenth century. Suffice it to say that population movements were extremely dynamic during the contact period reflecting new economic practices, political strategies, and military tactics.

The timing of contact and the composition of the social groups involved were related to the intentions of the colonizers and responses of the colonized. When sixteenth- and seventeenth-century French explorers were seeking a westward passage, they solicited information from Natives as to the existence of interior water routes that led to an inland sea. In the course of their initial chance encounters with Native peoples, they often exchanged goods of little economic importance to ensure safer passage and reliable information. When it became apparent that the existence of any such route lay far to the west, relations became less casual and more formal as each group saw the other as a potential ally in the larger political machinations that mark human groups everywhere.

As pointed out by Marcel Mauss nearly a century ago, economic exchanges in the form of gifts serve to solidify social relations, and European contact in North America was no exception. Inspired by the acculturation paradigm, archaeologists have used material remains acquired as gifts and in exchange to monitor various aspects of the contact experience. Europeans acquired a host of New World products and adopted associated practices; most of these have been examined as part of

North America During the European Contact Period, Fig. 4 Modern recreations of common eighteenth-century trade goods including kettles, firearms, axes, cloth and clothing, beads, and silver ornaments. (Photo by Barbara Cook)

a larger Columbian exchange that focused on the transfer of pathogens and domesticates for tobacco and maize. Considerably, more attention has been paid to the imported, European-manufactured goods that appear in trade lists and inventories of archaeological materials from post-contact Native sites throughout the continent (Fig. 4).

Despite earlier facile interpretations, archaeological studies have repeatedly shown that Native peoples were discriminating consumers who selected objects that were consistent with their belief systems. For example, at the Grimsby site, an early-seventeenth-century Native cemetery in southern Ontario, "the Neutral were in possession of a large amount of trade goods, but this material. . . had almost no impact upon the pattern of values and attitudes which we know as Neutral culture. The people were guided by their own way of doing things, by their own cultural configuration" (Kenyon 1982: 226). Similarly, none of the trade goods that were adopted by late-eighteenth- and early-nineteenth-century Indians along the Saskatchewan River and elsewhere in the West "were necessities for daily life. Indians [acquired goods that enhanced]. . . their repertoire of artifacts without eliminating their own manufactures" (Kehoe 2000: 181). Their basic way of life was not altered until after the devastating epidemics of the nineteenth century. As for new adoptions in clothing, Native women's readiness to adopt new styles was a pragmatic choice that reflected comfort, cheapness, and "appropriation of generally desired innovations" (Kehoe 2000: 183).

The presence of imported goods in Native sites often testifies to ways in which objects were adopted, transformed, and reinterpreted within a Native worldview. Yet, these seemingly practical choices also had unintended consequences. For example, copper-base kettles were commonly acquired by Natives after contact and were frequently buried with their owners or users at the time of death (Fig. 5). Kettles were subject to wear rendering them in need of repair until the end of their use life when they were frequently cut into ornamental shapes in the form of tinkling cones, hair pipes, or beads (Fig. 6). Such goods were exchanged over long distances and were often acquired by Native peoples well before they encountered Europeans themselves (Ehrhardt 2005). Kettles also afforded some people greater mobility. For example, when the Micmacs received copper kettles in exchange for furs, they were no longer tethered to large wooden caldrons for food processing and hence ranged further afield in search of furs thereby expanding their hunting territory (Martin 1975).

This and numerous other examples demonstrate how Indigenous peoples adopted European technology and used it in new ways that led to

cultural changes. Archaeologists may be hard-pressed to distinguish between processes of change and continuity as both are simultaneously at play. The adoption of alien goods challenges archaeologists to reconceptualize objects as having essential characteristics indicative of Native or European culture. Furthermore, some objects like tinkling cones and wampum had their genesis in the process of cultural exchange and are clearly products of cross-cultural interaction.

North America During the European Contact Period, Fig. 5 Brass kettles, like this eighteenth-century specimen from the vicinity of Fort St. Joseph, were often acquired by Native peoples and used in ways that were both intended and unintended by their European makers. (Photo by Roger L. Rosentreter. Courtesy of the Fort St. Joseph Museum Collection)

In late-seventeenth- to mid-nineteenth-century plantation contexts from the Chesapeake south to the Carolinas, archaeologists have recovered a distinctive ceramic type referred to as colonoware – a low-fired, often locally produced, hand-built earthenware (Singleton and Bograd 2000). Interestingly, it exhibits traits of both Indigenous and African ceramic traditions, often rendered into forms that appealed to British colonial tastes (Fig. 7). While archaeologists initially thought Indians made it, a growing consensus suggests that colonoware is a product of interaction constructed by both African and Native Americans. It exhibits certain preferable qualities that had practical advantages over iron pots and other kinds of cookware. Moreover, they were found "in the kitchens of planter families as well as in the cabins of slaves" (Singleton and Bograd 2000: 15). This example emphasizes the meaning of an artifact to the people who used it over who made it. It also points to the syncretism and cultural borrowing that characterized the contact period for several centuries.

While domestic settings often reflect the role of artifacts in daily use, mortuary remains represent a context in which Native peoples negotiated new social relations and manipulated material culture to express old and new beliefs in an effort to counter colonialism. Recent archaeological studies have shown that ritual acts and associated objects were significant elements in Native responses to the changing social and political

conditions brought about by European interactions (see Nassaney 1989, 2004).

In southeastern New England and elsewhere in North America, Native religious practitioners employed tobacco in sacred rituals to ensure spiritual and physical well-being. Social disruptions brought about by disease and warfare challenged Indigenous beliefs leading some segments of society to search for new ways to secure their own earthly or heavenly salvation. Archaeological and ethnohistorical evidence suggests that smoking became more widespread in Native society by the mid-seventeenth century as men, women, and children adopted it. While the expansion of the practice was facilitated by the introduction of widely available European-manufactured white clay pipes (Fig. 8), the reasons for the expansion of the practice were more complex than mere emulation of European recreational usage. Instead, there was an attempt to expand and redefine aspects of Native ritual activity to rectify a declining social and spiritual order (Nassaney 2004: 135). Women were active agents who sought to appropriate tobacco to rationalize the demographic, social, and political upheavals that Native communities experienced. Their efforts are visible in new artifact forms and changing mortuary patterns that signal an attempt to ameliorate the imbalances that Europeans caused.

Female use of tobacco in Native society was an attempt to connect with the cosmological forces that could help restore balance in an increasingly unintelligible world of death, animosity, and conflict. As tobacco use expanded in society, ritual became less institutional and more personal as the efficacy of religious specialists was called into question. The practice became popular among those who circumvented the hegemony of traditional healers and sought their own direct communication with spirit beings.

Pipes are not the only artifacts that had ideological significance for Native peoples under colonialism. Effigy pestles, which are long cylindrical stones with a sculptured representation at one end (Fig. 9), were made and used during the contact period in the greater Northeast (Nassaney and Volmar 2003). The recurrent association of these artifacts with women in death and in folk tales and the animals they depict suggests that these artifacts are symbols of female power that were first crafted in the seventeenth century. Furthermore, the creatures they depict evoke mythological symbols of supernatural beings that signal women's social position in Algonquian society. In the onslaught of a crumbling social order that challenged the predictability of roles and relations, it appears that individuals developed new ways to make contact with other worldly forces

North America During the European Contact Period, Fig. 9 Effigy pestles recovered from archaeological sites in southern New England seldom exhibit utilitarian wear suggesting they served a different function. This bear effigy was recovered from the Burr's Hill site, an eighteenth-century Wampanoag cemetery in Warren, RI, along the eastern shore of Narragansett Bay. (Drawing by Pamela Rups)

and beings as a way to rectify an unstable situation represented through mortuary ritual and effigy pestles.

Native peoples exhibited cultural flexibility and resilience by incorporating many Western forms of material culture into their way of life (e.g., white clay pipes). Yet many core features of Native culture persisted. Despite a decrease in their numbers and land base and the encroachment of colonists, they retained and reshaped their ethnic identities as they sought to remain autonomous communities (Kicza and Horn 2013: 184).

One means of ensuring cultural and biological survival in the contact period was the interethnic unions formed between individuals – the most intimate of interactions. Mixed-race groups emerged in the form of Spanish *mestizos*, French *métis*, and Russian Creoles. Most often, they were the offspring of Native women and European men. Loren (2010) has examined how this new identity was expressed archaeologically through the medium of clothing and adornment. She finds archaeological, historical, and ethnographic examples of attire that reveal a pattern of varied small finds such as shell ear pins, tinkling cones, and brass buttons worn by people who exhibited mixed fashions (Loren 2010: Fig. 2.6); this intimates that disparate clothing styles were the norm for some segments of society despite sumptuary laws that prohibited them. She posits that this sartorial stance "allowed individuals to move through complex and socially restrictive colonial landscapes to create new identities" (Loren and Beaudry 2006: 266). The consumption of goods played a central role in identity formation in culturally mixed settings; objects enabled "people to locate others within social fields through the perception of embodied tastes and various indexical forms of symbolic capital" (Dietler 2005: 64).

The material manifestations of colonial entanglements are clearly revealed in the archaeological record, particularly in the objects of daily life that were used and discarded; these materials are indicative of other cultural changes that permitted both Natives and newcomers to persist. For example, cloth was among the most frequently traded commodities by value and volume, despite the abundance of less perishable iron, brass, and glass artifacts in the archaeological record. The acquisition of cloth contributed to a decline in the production of leather and hide clothing, which were labor-intensive tasks that were predominantly women's work (Anderson 1994). Thus, women could reallocate their labor to other activities, perhaps associated with processing furs for the burgeoning European market or embroidering beads onto garments using distinctive Native motifs. Thus, Indigenous labor often focused on a more limited range of activities, sometimes driven by European demands. Rogers (1993) documented a major decline in Arikara artifact categories linked to several activity sets such as scraping, pounding, knapping, and chopping among others and an increase in many of the Euro-American activity sets on the Northern Plains in the first third of the nineteenth century. This pattern suggests discontinuities in activities as a consequence of social disruptions caused by contact.

Some European goods acquired in exchange for furs were substitutes for Native counterparts,

North America During the European Contact Period, Fig. 10 An elaborate lapidary industry developed in New England after contact once Natives gained access to metal files. Stone pipes were among the objects produced, including this specimen from the Burr's Hill site, in Warren, RI. (Drawing by Pamela Rups)

but many were used in distinctively Native ways. Some objects (e.g., military attire) served as markers of newly emergent political statuses, which increased social inequalities, whereas other commodities (e.g., iron drills, files) facilitated the intensification of wampum production and a lapidary industry used to create elaborate forms of smoking pipes (Fig. 10). Commodity exchange affected Native groups in two other related ways. First, imported goods often replaced Native goods freeing up time for Native producers to reallocate their labor, as in the case of the adoption of European cloth. Second, Native peoples channeled their labor to produce goods that Europeans wanted to acquire. For instance, the English were eager to obtain maize from Native trading partners in the early stages of their interactions in southeastern New England. Later on, they demanded increasing quantities of wampum to secure economic stability and increase political influence in the region. Thus, Native participation in the fur trade had a significant influence on the ways in which labor was allocated and organized. By the end of the seventeenth century, the events of the colonial encounter that left many people landless made it impossible for them to maintain an economy that reflected an earlier (i.e., precontact) division of labor and enticed them into becoming wage laborers. But Native peoples were responding to these new conditions even before they became dispossessed.

Native efforts to meet European demands for deer hides in the Southeast are reflected in butchering patterns observed on deer carcasses during the seventeenth century in the Ridge and Valley province of the Appalachian Highlands. Some sites "show a greater reliance on white-tailed deer and a decline in the diversity of non-fur-bearing animals" as a result of participation in the deerskin trade (Lapham 2005: 22). Native hunters developed a selective predation strategy intended to procure deerskins specifically for commercial trade (Lapham 2004: 189). Evidence of intensified processing activities throughout the region is also reflected in the increased production and use of beamers – bone tools "used to scrape hair and fatty debris from deerskins during the initial processing stage" (Lapham 2005: 23). Finally, deer bones exhibit cut marks consistent with skinning to maximize the size of the hide that was removed intact.

In sum, new production activities that developed to fulfill European desires led to the acquisition of manufactured goods that effectively replaced their Native counterparts soon after contact. Metal knives, axes, and drills quickly replaced many types of stone tools (Nassaney and Volmar 2003). Metal hoes also became common, although some elderly women resisted their adoption and sought to retain their shell equivalents in seventeenth-century New England. The broad range of European cloth types at a Narragansett Indian cemetery may be taken to indicate that cloth became widely available after 1650. Brass kettles and imported ceramic containers made Native ceramic technology nearly obsolete by the end of the seventeenth century in the Northeast and the Midwest, though it apparently persisted in areas of the Southeast well into the

nineteenth century. Caddoan ceramics in east Texas were produced until 1805 and were common on Spanish mission sites, suggesting the incorporation of Native elements into the mission system (Perttula 1993: 104). While generalizations can be offered for the observed patterns, it remains necessary to examine localized contexts to illuminate why some practices and goods were absorbed into the everyday lives of people, while others were ignored, rejected, or contested (Dietler 2005: 62).

European contact also had profound ecological consequences that are reflected archaeologically. Cronon (1983) examined the impact of the introduction of new species on Native societies. While some groups were reluctant to adopt Old World domesticates, remains of cow, sheep, swine, chicken, and various imported plant foods like peaches and watermelons have been recovered from Native sites throughout North America. Furthermore, the behaviors of large ungulates like horse, pigs, and cattle threatened the habitats of animals that Native peoples depended upon with deleterious effects on Native subsistence strategies.

The demands brought about by the commercial harvesting and processing of animal resources, especially as related to the fur and deerskin trades, often led to overexploitation. Native peoples responded by relying on alternate species, moving their settlements, or engaging in wage labor. The Dutch arrived in New Netherlands in 1624, and trading posts were soon established on the Connecticut and Delaware rivers. Yet the decimating effects of the early fur trade forced the Dutch to move their posts upriver when coastal beaver populations were overhunted (Brasser 1978: 82). The outcomes of overexploitation drove fur traders and Native hunters further inland and upriver throughout the seventeenth and eighteenth centuries. Commercial hide exploitation redirected exchange networks, altered political alliances, created political factions, reshaped gender relations, and transformed belief systems (Lapham 2004: 191). The forces set into motion during the contact period had enduring effects.

Future Directions

North America during the European contact period has been well documented through the writings of explorers, settlers, soldiers, and missionaries. However, this record reflects the perceptions of a small, literate segment of the population. Natives passed down their experiences after contact through oral traditions, though these are often inaccessible to researchers who have either neglected to consult them or have been unable to decode them for historical and anthropological information. While both documentary sources and oral accounts have great potential to inform on the North American contact period, both Natives and newcomers left an equally important body of data that can be exhumed and interpreted to examine what happened in the past and who was involved. While archaeology is fragmentary by its very nature and subject to its own set of biases, it "offers a continually evolving database that can serve as a crosscheck against insights gained through other approaches" (Nassaney and Johnson 2000b: 5). Artifacts are also multidimensional symbols, insofar as they express technological, social, and ideological aspects of culture simultaneously. It is their multivalency that makes them such powerful interpretive tools.

Thus, archaeology can furnish evidence about the contact period that is different from and independent of the colonial texts of historians (Dietler 2005: 50). It can reveal the subaltern histories that were created alongside the dominant narratives and in so doing, contribute to the historical experiences of marginalized groups. This has long been a hallmark of historical archaeology. Recent archaeologies of colonialism have continued to examine the "conditions surrounding Indigenous peoples' engagement with Europeans and the impacts of those entanglements on material and social identities" (Nassaney 2012: 6). Some have concluded that the collaborative study of colonial contexts can work to decolonize archaeological practice by promoting a redistribution of power and authority through the creative flow of knowledge among different partnering groups (Atalay 2006; Nassaney 2012).

Should archaeology continue to follow this direction, it will become increasingly emancipatory by providing a conceptualization of the contact period that aims to "pay homage to hybridity, emphasize cultural fluidity, acknowledge human agency, and empower contemporary cultural groups who have a stake in the history of. . . the colonial enterprise" (Nassaney 2012: 17). Archaeologists of this ilk will become receptive to the concerns of stakeholders who have a vested interest in the analysis of the contact period impelling efforts to be more inclusive in practice. Even in the absence of direct collaboration "non-Indigenous archaeologists need to help each other develop the capacity to witness how we reproduce a colonialist discourse" as they "examine and rectify their own colonial practices and work toward a broader reconciliation between their practice and the stakeholders with whom we share an interest" (Nassaney 2012: 18).

Archaeology of the North American contact period is still in its infancy, but it will come of age by embracing right relations. This will require practitioners to face up to the colonialist legacy so that we can all recover from it, engage in the process of healing, and make ourselves whole. There is a profoundly spiritual dimension to the work of interpreting the North American contact period. Archaeologists hold the tools to amend past wrongdoings and create greater equity in a way that restores dignity to all the historical agents who became entangled in contact, whether of their own doing or not.

North American Classification Schemes: Overview

Phillip D. Neusius and Sarah W. Neusius
Anthropology Department, Indiana University of Pennsylvania, Indiana, PA, USA

Introduction and Definition

North American archaeology can be defined as the study of the material remains of past North American peoples and restricted to areas north of central Mexico, mostly in the United States and Canada. Although this field did not develop in complete isolation from European archaeology or from research on the civilizations of Mexico and other parts of Central and South America, it has several distinctive and interrelated features (Willey and Sabloff 1993).

First, from its beginnings in the antiquarianism of the eighteenth and nineteenth centuries, North American archaeology has focused on scientific questions such as those related to artifact typology, geography, and stratigraphy rather than on art, iconography, and other more humanistic topics. These emphases can be attributed to the levels of human sociocultural organization observed among North American Indians at

N

European contact and evidenced in the material remains of North America. When compared to peoples in Central and South America, North Americans have been perceived as relatively less complex socioculturally, and their study has fallen largely within the tradition of natural history. This orientation continues to this day despite growing recognition of the limitations of evolutionary typologies and contemporary interest in iconography and religion.

Second, until the latter third of the twentieth century, North American archaeologists primarily focused on the prehistoric past rather than on the historical developments following the arrival of Europeans in North America. Despite the tremendous potential for investigation of historical topics, most North American archaeologists have studied prehistory, all the while seeing North American prehistory as largely cutoff from history and understanding the cultures of contemporary Native American descendants as too modified to provide many significant insights into the past. Coincident with the development of a robust historical archaeology of North America over the last few decades, the indigenous people of this continent have increasingly asserted their interest in and relevance to the archaeology of their ancestors. Both of these developments have had major effects on theory and practice and made it clear that the traditional classificatory schemes employed by North American archaeologists and discussed in this entry may not be heuristically sufficient.

Finally, in North America, archaeology is understood as one of the four fields of anthropology. The commitment to a four-field anthropological approach developed by the Boasian school of anthropology in the early twentieth century has defined how archaeology has developed in North America. In this school of thought, culture was understood as divisible into distinct units or cultures with unique characteristics and histories and bound together by norms of behavior. In turn, North American archaeology can be understood as an investigation of the past cultures of the Native Americans being studied by ethnographers. In fact, in the early twentieth century, anthropologists studying indigenous peoples often did both ethnographic and archaeological research. At this time, documenting customs, language, biology, and material culture, before what was thought to be the inevitable further loss of culture, were all seen as essential pursuits for the anthropologist, and archaeology was part of this process. Most North American archaeologists are still trained in anthropological holism and view themselves as contributing to the field of anthropology. Today, even though the unit concept of culture has been questioned, most contemporary North American archaeologists still understand archaeological evidence as culture and focus their research on investigations of material culture as a means of understanding the cultures of the past.

Given these perspectives, a central problem has been how to organize the North American archaeological record into meaningful cultural units for productive investigation and scholarly communication. Such cultural units have been perceived as more or less mirroring cohesive subdivisions of the past cultural world. Their grouping into classificatory schemes at various temporal and spatial scales also has been considered a legitimate means of summarizing as well as understanding the past. Methodology for creating classification schemes developed within the normative framework, a historical approach to culture that dominated anthropological theory in the early twentieth century. This normative approach defines culture as shared ideas, beliefs, values, customs, and artifacts. Anthropological and archaeological theory has moved beyond this approach, but North American archaeology continues to use basic classificatory schemes relying on the dimensions of space, form, and time recognized by the culture historians of the first half of the twentieth century. Although often questioned and nearly universally considered limited in their accuracy in representing the past, these classificatory devices remain in use for want of superior methods. Familiarity with these schemes is central to understanding the field of North American archaeology.

Historical Background

Space and the Development of the Culture Area Concept

Although nineteenth-century scholars understood that there had been geographically circumscribed cultural expressions within North America such as Hopewell or Fort Ancient in Ohio (Trigger 2006: 279–280), inclusive geographic means of understanding North American indigenous cultures first developed around the turn of the twentieth century when the concept of culture areas was developed (Holmes 1914; Wissler 1926). These formulations had the practical advantage of providing a way of organizing ethnographic and archaeological collections for museum display and study that was not dependent on the unilineal evolutionary typologies that were then falling out of favor among anthropologists. The translation of these culture area schemes from ethnographic regions to the prehistoric past was seamless because, at this time, North American scholars did not believe there was any great time depth to the Native American past. These formulations gave more importance to natural or environmental features than to historical or evolutionary trajectories, but in order to avoid falling into a simple geographical or environmental determinism, they relied on diffusion from cultural centers to explain the distribution of cultural traits.

Perhaps the most important work on the concept of North American culture areas was Kroeber's *Cultural and Natural Areas of Native North America* originally published in 1939, but republished several times because of its seminal significance (Kroeber 1963). Kroeber defined the culture areas of North America in terms of meticulously enumerated cultural traits, an approach that lent itself to subsequent statistical analyses (e.g., Driver and Massey 1957). He took pains, however, to point out that his focus was on whole cultures rather than traits per se. Kroeber also was not an environmental determinist, and he wrote before the development of theory in cultural ecology (Steward 1955) that would greatly impact North American archaeology. He notes that although cultures cannot be completely understood without reference to their natural context, "the immediate causes of cultural phenomena are other cultural phenomena" (Kroeber 1963: 1). His focus was on the delineation of cultural climaxes within the commonly recognized North American culture areas; these were examples of what he called cultural intensity or points "from which the greatest radiation of culture material has taken place in the area" (Kroeber 1963: 223).

By the mid-twentieth century, it was clear that culture areas could not necessarily be defined by the distribution of archaeological traits. However, the practice of using natural areas as a means of bounding archaeological regions or, as suggested by Rouse, of identifying one's data with the cultural center it most closely resembled continued among archaeologists (Webster 2008: 17).

Over time thinking about Native Americans in terms of culture areas has become convention within both North American archaeology and ethnology. No matter that the theoretical basis of this approach in environmental possibilism and diffusionism has long been repudiated by North American archaeologists. North American archaeologists recognize that cultural centers and boundaries cannot really be projected backward in time over many millennia. They also recognize that within culture areas at any given point in time, actual cultural diversity was greater than these formulations imply, and particular cultural groups may not fit the generalities for a given area. Today, as the normative idea of culture has been challenged, and many contemporary archaeologists focus on variability rather than classification, the limitations of the concept of culture area are clear. Nonetheless, North American archaeologists continue to find culture area designations useful in organizing their data. Scholars define their regional specialties in terms of these areas, and they are used in introductory textbooks on North American archaeology.

North American archaeologists commonly recognize ten pre-Columbian culture areas with the

North American Classification Schemes: Overview, Fig. 1 Native American culture areas

boundaries defined more or less as shown in Fig. 1. These areas are the Arctic, Subarctic, Northwest Coast, Plateau, California, Great Basin, Southwest, Plains, Southeast, and Northeast culture areas. Commonly accepted generalizations about the cultures of these areas are also summarized in Table 1 although cultural variation actually was greater than this table implies.

Formal Variation and Temporal Change

Early twentieth-century American archaeologists focused on formal variation as they tried to make

North American Classification Schemes: Overview, Table 1 Characteristics of the North American culture areas

Culture area	Generalizations related to economy and material culture	Generalizations related to sociopolitical organization and religion
Arctic	Exploitation of sea mammals, caribou and fish; tailored clothing, elaborate harpoons, umiaks, kayaks, and dogsleds; wood, stone, sod, and snowhouses	Organization into bands; bilateral descent; shamans
Subarctic	Exploitation of caribou, moose and fish; semi-tailored clothing and snowshoes, toboggans, bark canoes, basketry; lean-tos and rectangular log-frame houses, conical tents	Organization into bands; bilateral, matrilineal and patrilineal descent; shamans, shaking tent divination
Northwest coast	Exploitation of salmon, sea and land mammals; elaborate woodworking, dugout canoes; rectangular, plank, multifamily houses; elaborate masks	Villages, social classes, slaves; matrilineal and patrilineal descent; potlatches, elaborate ceremonies
Plateau	Exploitation of salmon, game and roots; basketry, bark fiber clothing; semi-subterranean winter pithouses and reed or mat-covered summer houses	Villages; bilateral descent; shamans, diverse spirits
California	Exploitation of acorns, mesquite beans, game, and marine resources; basketry, seed-grinding stones, sinew-backed bows; brush, bark and grass shelters	Bands and tribes, ranked societies along southern coast; bilateral descent; shamans, elaborate female puberty ceremonies
Great Basin	Exploitation of pine nuts, rabbits and antelope; basketry, seed-grinding stones, sinew-backed bows, nets for land mammals; brush, bark and grass shelters	Bands; bilateral descent; shamans, elaborate female puberty ceremonies
Southwest	Cultivation of maize, beans, and squash as well as exploitation of game and domesticated turkeys; irrigation; pottery and basketry, cotton garments; multiroom pueblos	Villages; matrilineal and bilateral descent; elaborate ceremonial round, kivas, masked dancers
Plains	Cultivation of maize and beans as well as exploitation of bison; bone and skin-working, dog-drawn travois, game surrounds, hide shields; skin tipis	Bands; bilateral, patrilineal and matrilineal descent; vision quests and guardian spirits
Northeast	Cultivation of maize, beans, and squash as well as exploitation of game and fish; hide clothing, bark canoes; wigwams and multifamily longhouses, palisades	Tribes and confederacies; matrilineal and patrilineal descent; secret societies, seasonal ceremonial round, dogs eaten ceremonially
Southeast	Exploitation of maize, beans, and squash and exploitation of game and fish; clothes made of feathers over netting, storage facilities, rectangular multifamily structures, fortifications	Tribes, confederacies, chiefdoms; matrilineal descent; complex ceremonies, sun worship, priests

(After Oswalt 2009: Table 1.1).

sense of the increasing array of materials from archaeological survey and excavation. While archaeologists in the Southwestern United States took one direction focusing on stratigraphy and chronology, other North American archaeologists were focusing on formal variation alone to create taxonomies.

In the Southwest, Kidder (1924) and others were creating ceramic types based on attributes with temporal variation through the use of stratigraphic control and seriation. The growing use of the stratigraphic method led to the increased use of metrical rather than natural stratigraphic controls during excavation. There was considerable debate over the reliability of using arbitrary excavation levels. These methods led Kidder to start developing a broad cultural chronology which culminated in the Pecos Conference in 1927, a

North American Classification Schemes: Overview, Table 2 Pecos classification as originally defined

Original period	Traits
Pueblo V (historic)	AD 1600 to present
Pueblo IV (proto-historic)	Widespread abandonment, decline in artistic elaboration, plain pottery wares
Pueblo III (great pueblo)	Very large communities, artistic elaboration, and craft specialization
Pueblo II	Small villages, pottery corrugated over entire surface
Pueblo I (proto-pueblo)	Above ground structures of contiguous, rectangular rooms, pottery with unobliterated coils or bands at neck, cranial deformation
Basketmaker III (post Basketmaker)	Pithouses or slab houses, plain pottery, no cranial deformation
Basketmaker II (Basketmaker)	No pottery, but agriculture and atlatl present
Basketmaker I (early Basketmaker)	Preagriculture, no longer in use and considered the archaic

meeting of the leading archaeologists working in the Southwest to create a chronological classification system that could be used throughout the Southwest. The result was the Basketmaker I–III/Pueblo I–V sequence still used in modified form in the northern Southwest. As shown in Table 2, this nomenclature was based on a taxonomic classification of architecture, community patterns, pottery styles, and other artifacts. In noting that the "Pecos Classification" was more a pattern of cultural change than a chronological scheme, Winifred and Harold S. Gladwin criticized the system for its lack of applicability to areas outside of the northern "Pueblo" area such as the Hohokam and Mogollon regions. Gladwin proposed a classification based upon a tree analogy with three major roots (Anasazi, Hohokam, and Mogollon), leading to a variety of stems, branches, and phases (Gladwin and Gladwin 1934). While this taxonomy was based primarily on "cultures" grouped together because of similar traits, it also relied upon geography in its formulation. The chronology was assumed in the nature of the tree analogy with roots preceding stems and so forth.

At the same time, other North American archaeologists also were struggling with creating taxonomies that would help them to sort the increasing amount of data being generated by archaeologists. The most influential of these efforts was the Midwestern Taxonomic System, sometimes referred to as the McKern Classification (McKern 1939). Although linked to McKern, this taxonomic system was the result of a decade of debate among Midwestern archaeologists about the need for a common classification system to aid in comparative studies. One unique aspect of this classification as opposed to the Pecos Classification was its specific exclusion of time and space as defining attributes. Instead this system was designed to rely on "determinants,"' diagnostic traits that could be used to distinguish "manifestations" of culture. This grouping of determinants could then be used to create a classification to distinguish cultures. This resulted in the levels of classification noted in Fig. 2.

Although the Midwestern system initially ignored time and space, an important implicit assumption was that this strict taxonomy would eventually relate to time and space. In this context, an archaeological culture was based upon shared physical characteristics. The goal was to distinguish these cultures which would then occupy distinct times and places.

These initial classifications based upon the variability in formal attributes all had a similar concern in terms of trying to distinguish archaeological cultures and establish a sequence of culture change. This initial concern was linked to the lack of data early North American archaeologists had about the sequence of events or about different groups of people. However, by the mid-twentieth century, archaeologists were starting to focus on what these "typologies" represented in terms of function and cultural context. Julian Steward and Frank Setzler (1938) in their article titled "Function and Configuration" were among the first to note a lack of focus by archaeologists on understanding or describing cultures. They criticized archaeologists for focusing too much on building artifact chronologies without considering the culture that produced the artifacts.

North American Classification Schemes: Overview, Fig. 2 Units of the Midwestern classification

Archaeologists also were debating what the formal typologies they created actually represented. Some, including Ford (1954), suggested that typologies were simply useful tools abstracted by the archaeologist to answer their specific research questions. Spaulding (1953) and others argued that archaeologists could derive types that had demonstrable meaning for the people of the past. Rouse (1960) suggested ways in which types could be either abstracted by the researcher or discovered as part of a past culture. Rouse proposed these as two different ways to classify artifacts. Analytic classification could be used to discover the modes of a culture. Taxonomic classification involves using different modes (attributes) to create types meaningful to the archaeologist's research question. For example, if you are creating temporal types, you only use those modes that reflect variation in time and space, such as the shape of a projectile point. But if you are interested in reconstructing lifeways, you might use another mode such as raw material type for these projectile points.

Until 1928, North American archaeologists generally thought that humans had a relatively brief presence of only a few millennia in North America. Then, a fluted spearpoint was discovered embedded in the rib cage of an extinct bison skeleton being excavated at Folsom, New Mexico. This find established an Ice Age presence for humans in the Americas and made the question of temporal variation much more significant.

Nevertheless, through most of the first half of the twentieth century, American archaeologists had to deal with temporal variation by relying on relative dating techniques such as stratigraphy, seriation, and typology. With the development of absolute dating techniques by the 1950s, such as tree-ring dating in the Southwest and radiocarbon dating for the rest of North America, archaeologists not only had a key to building chronological sequence, but could measure the time depth of

human occupation in the New World inferred from the Folsom find.

About this same time, Willey and Phillips (1958) attempted to bring the diversity of perspectives on American archaeological method and theory together into a more coherent classification. The focus in American archaeology had been on culture history, attempting to order the archaeological record into a sequence over time and space. Willey and Phillips proposed what they called an "Operational Basis for Culture-Historical Integration" as an attempt to define the way archaeologists actually use the dimensions of time, space, and form. In this volume, they defined only two basic archaeological units for classification, the component and the phase. These were common terms used in archaeology, but Willey and Phillips tried to more precisely define their use in archaeology as the elements of formal variation. The component is the single manifestation of a culture at an archaeological site. They define the phase as "an archaeological unit possessing traits sufficiently characteristic to distinguish it from all other units similarly conceived, whether of the same or other cultures or civilizations, spatially limited to the order of magnitude of a locality or region and chronologically limited to a relatively brief interval of time" (Willey and Phillips 1958: 22).

Willey and Phillips also operationalized terms for space (site, locality, and region) and time (local sequence and regional sequence). These provide the context for the basic archaeological units of phase and component. Beyond these basic units, they provide what are called integrative units of horizon and tradition. The horizon marks traits and assemblages whose distribution in space suggests a rapid spread over a broad area. The tradition is a temporal continuity represented by persistence in technologies or related forms.

Taken together these concepts were meant to help archaeologists construct local and regional culture histories. But in this volume, the authors took it a step further in response to the neo-evolutionary approaches becoming popular at mid-century. They propose the use of a "Historical-Developmental Approach" (Willey and Phillips 1958: 61). It is here that they propose a series of developmental stages distinct from periods. While the term period refers specifically to chronology, the stage can be defined by content regardless of time. These developmental stages

North American Classification Schemes: Overview, Table 3 North American stages as defined by Willey and Phillips

Willey and Phillips stages	Characteristics defined by Willey and Phillips	North American expressions
Postclassic	Breakdown of classic styles and culture, continued urbanization but militarism, secularism and warfare, interregional transference of styles but aesthetic decline	None
Classic	Beginnings of urbanism, florescence of material culture, climax in architecture and sophisticated art	None
Formative	Development of agricultural lifeways especially maize agriculture, sedentary village life, minimal social complexity	Hohokam, Anasazi and Mogollon in the southwest; woodland mound building cultures of the northeast and southeast, primarily middle woodland, Mississippian developments; possibly Plains Village cultures
Archaic	Migratory hunting and gathering cultures in increasing modern environments, addition of groundstone as well as bone technology, small but sometimes longer-term settlements, diversification of subsistence pursuits	Eastern archaic, plains archaic, southwestern archaic, desert archaic and probably maritime cultures of the California and northwest coast
Lithic	Initial adaptation to new world environments, reliance on rough and chipped stone tool technology, small-scale, mobile societies, emphasis on hunting	Paleoindian

are defined as descriptive although "founded on common participation in important historically derived traditions" (Willey and Phillips: 64). They were intentionally trying to avoid the common criticism of being unilineal evolutionists. The five stages of development they proposed for American archaeology are Lithic, Archaic, Formative, Classic, and Post-Classic (Table 3). Willey and Phillips saw this descriptive process of defining formal variation, plotting it in time and space, and identifying their functions and relationships as "archaeology's primary tasks, on the descriptive level of organization" (Willey and Phillips 1958: 61). Although they recognized the need for explanation in archaeology, they did not propose any archaeological methods for achieving this.

The culmination of this approach can be seen in Willey's seminal work *An Introduction to American Archaeology, vol. 1: North and Middle America.* In his Introduction, Willey states "The intent of the book is history—an introductory culture history of pre-Columbian America" (1966: 2). As such he has demonstrated the utility of the classificatory methods espoused in the Willey and Phillips volume. At the same time he specifically notes, "I shall be less concerned with process or a search for cultural 'laws' than with at times attempting to explain why certain cultural traditions developed, or failed to develop, as they did." The goal of his synthesis was culture historical-developmental interpretation, not explication of culture process.

Key Issues/Current Debates

In a general sense, these concepts defined by Willey and Phillips are still being used by North American archaeologists today. Archaeologists are still defining components and phases or horizons and traditions. However, in many regions, the way in which these terms and especially the stage concept are operationalized has been modified. For example, the lithic stage is usually referred to as the Paleo-Indian period, and while the Archaic is referenced by most archaeologists, it is as likely to be called a period as a stage. North American archaeologists generally do not use the concept of a Formative stage, although they do recognize the development of agricultural societies in the Southwest, the Plains, the Northeast, and the Southeast. In the Southwest culture area, horticulture was important in the various regional traditions (e.g., Ancestral Pueblo and Hohokam) that developed after approximately CE 200. In the Plains, the Northeast, and the Southeast, Woodland cultures after approximately 1000 BCE can be considered to parallel the Formative. In all these regions, experimentation with plant cultivation and domestication began in the Archaic, but the cultural characteristics associated with the Formative by Willey and Phillips are more fully evident after the Archaic. In the Western parts of the United States, there is little evidence of a Formative. However, settled life and the development of social hierarchies did develop in some areas. Along the Pacific Coast, complex hunter-gatherers, who developed social ranking, had hereditary chiefs, and lived in large, settled communities, are found in the later pre-Columbian times. Neither the Classic nor the Post-Classic was recognized as occurring in North America by Willey and Phillips, and North American archaeologists do not use these concepts at all. Nevertheless, Willey and Phillips' "primary task" of formulating archaeological units that are assumed to represent cultural units has not been abandoned.

Continuing Methodological and Theoretical Developments

The advent of the "new archaeology" in the 1960s altered perceptions of Willey and Phillips' approach. Since most North American archaeologists remain basically processualist theoretically, this critique of culture history is entrenched in the thinking of North American archaeologists even today. The essence of the processualist critique of attempts at classification involved defining earlier archaeologists as culture historians who saw the ordering of cultures in time and space as the primary goal of archaeology. Processualists did not so much reject the classification methods of culture historians as make an argument that this was not the only contribution of archaeology to

the understanding of past cultures. Classification of assemblages into components and phases and their grouping into larger units such as traditions and stages was understood to be a descriptive step that preceded the reconstruction of past lifeways and ultimately the exploration of questions of culture process. As anthropologists, processualist archaeologists were more interested in how culture functioned and explaining the process of change than in the ordering of components and phases. Nevertheless, it was believed necessary to build on culture history to accomplish these loftier ends (Leone 1972: 26). As a result, the classificatory schemes, including local phases and regional traditions and the stages proposed by Willey and Phillips, have continued to be utilized in North American archaeology. Perhaps because of processualism's disdain for culture-historical analyses of chronology and time-space systematics, many of the specific archaeological units North American archaeologists still employ have not been critically evaluated.

A systemic, adaptive approach led processualists to view archaeological phases as rough equivalents of cultures. In this view, the archaeological record provides evidence of cultural systems which in turn can be characterized by particular adaptive strategies. Culture change results from factors such as environmental change or human population growth which upset the systemic equilibrium. Influenced by neoevolutionary thought as well as the variability evident in a growing body of data, some archaeologists rejected Willey and Phillips' stage concepts. These North American archaeologists have argued that North American archaeological data should be grouped into periods of time rather than the stages of cultural development. In practice, however, periods often have been treated as being characterized by cultures having the attributes of Willey and Phillips' stages, and evolutionary assumptions have been implicit. For example, the Archaic period peoples of North America have been characterized rather universally as small bands of seasonally mobile hunter-gatherers even though the growing body of data on the Archaic indicates considerable diversity in economic, sociopolitical, and ideological traits (Emerson and McElrath 2009).

Thus, although the "new archaeology" of the late twentieth century criticized the approach of earlier culture historians, processualists used many of these concepts as a starting point for their attempts at explanations of culture process. More recently, in the twenty-first century, archaeologists from a variety of theoretical perspectives are rejecting these basic unit concepts outright, noting their asynchronic and nomothetic nature. The new evolutionary archaeology proposed by Dunnell (1978) and others rejects the notion of starting with cultural units in favor of defining specific traits and tracking the adaptedness of traits rather than cultural units. On the other side of the theoretical spectrum, these culture unit concepts are also rejected by postprocessualists because of the lack of concern for the individual and the role of agency in a dynamic cultural system. There is also the criticism that working from a culture unit concept constrains a variety of explanatory frameworks, such as ideology, art, religion, or even gender.

Future Directions

Given recent assaults on the theoretical assumption that unit cultures exist as discrete, stable entities in the past and present, it might be expected that traditional classificatory schemes, resting on this very assumption, would be abandoned. However, there are aspects of the practice of North American archaeology in the twenty-first century that fosters the continued use of these classificatory schemes. First, processualism, albeit a modified processualism that has been influenced by the postprocessualist critique, remains the basis for the majority of North American archaeology (Hegmon 2003). Given the view that establishing the regional culture history is a basic step that precedes more sophisticated analyses, North American archaeologists still utilize these classificatory units.

Second, and perhaps most importantly, the development of cultural resource management (CRM) has encouraged the continued use of recognized units of culture history such as phases and traditions. Since the 1960s, a series of laws in both the United States and Canada have explicitly

defined archaeological sites as well as historical structures as cultural resources that must be managed for the benefit of society at large. Today, the vast majority of archaeology done in North America is done to define which resources are important enough to be protected from the processes of development. Alternatively, the effects of development must be mitigated through thorough excavation or recordation of these sites and structures (King 2008). Traditional academic archaeology done for research sake certainly persists in universities and museums, but most archaeologists work for government agencies, engineering, or archaeological firms in the growing industry generated by CRM laws. One result of this trend has been the frequent disengagement of many practicing archaeologists from the meta-debates about archaeological theory and method going on in scholarly circles. Thus, the critique of the unit culture assumption has not been thoroughly examined by those doing the majority of the archaeology taking place in North America.

Moreover, the requirements of CRM archaeology, which include efficiently assessing the significance of sites and their assemblages in a timely manner, lend themselves to fairly simplistic adoption of the classificatory schemes developed by culture historians. It is easy to conceptualize the task of the CRM archaeologists as filling in missing gaps in our knowledge of past cultural entities through archaeology. This is, of course, not an entirely a theoretical undertaking, but theory may seem to have a less obvious place in this kind of work especially to harried practitioners working for clients with deadlines. These circumstances encourage the writing of reports that rely on boiler plate descriptions of cultural phases and regional traditions defined in state preservation plans. Such reports may fit the results of survey and excavation into existing classificatory schemes uncritically. There may also be a tendency to define the job of the CRM archaeologists as generating data, which can be utilized by others in synthetic and regional evaluations that are outside the CRM practitioner's purview. Whether or not such synthetic work ever actually happens seems less important than completing reports and moving on to the next project.

Third, a reengagement with culture-historical classification stems from the increasing interest of Native Americans in archaeology. The need to correlate material culture and its distribution with specific historical ethnicities has increased rather than decreased in the age of the Native American Graves Protection and Repatriation Act (NAGPRA). At the same time, the ethical awareness of North American archaeologists that consultation and collaboration with descendant populations is desirable has grown. This has reinforced the importance of the systematics of culture history (Webster 2008). Some of the same archaeologists, who critique the normative culture unit assumptions employed in traditional classification and seek multivocal interpretations of the past, recognize the need to identify ethnicity in the archaeological record. As imperfect as culture history classifications are, they remain the starting point for much of this discussion. Fortunately, in pursuit of ethnicity, archaeologists are much more likely to critically evaluate regional schemes of culture history.

For these reasons, the traditional North American classificatory schemes are likely to remain important in the actual practice of North American archaeology despite calls for focusing less on culture as a normative whole. Thus, it remains important for archaeologists studying prehistoric North America to understand the nature and formulation of these units.

North American archaeology's traditional classification schemes were developed in the first half of the twentieth century around concepts of space, form, and time. Culture areas within which cultures tended to be similar were recognized first, and they continue to be referenced today despite general understanding that they do not begin to capture the true variability and nuance of past cultures. The concept of unit cultures recognizable in the distribution over time and space of material culture traits was developed by the middle of the twentieth century. These formulations recognized components and phases that can be grouped into regional traditions and horizons. Ultimately, these classificatory units have been thought to relate to stages of development or to prehistoric periods. Despite recognition that these

units mask variability and debate about the underlying concept of unit cultures, these units are still employed by North American archaeologists.

While the continued sway of processualism among North American archaeologists as well as the growth of CRM archaeology may encourage less than critical use of regional schemes for phases and traditions, the sociopolitics of contemporary North American archaeology also encourage a renewed interest in the recognition of ethnicity in the archeological record. These research interests, which often lead to a critique of the concept of unit cultures altogether, are more likely to generate critical reevaluation of the culture-historical classifications used by North American archeologists.

North American Megafauna Extinction: Climate or Overhunting?

Gary Haynes
Department of Anthropology, University of Nevada, Reno, Reno, NV, USA

Introduction

Around 50,000 years ago, North America was home to 48 genera of large terrestrial mammals. But by 10,000 years ago, 36 of those genera had become extinct (Table 1). The disappearance of such a huge proportion of animal types is bewildering. By far, most of the extinct genera were "megafauna," which are animals having an adult body mass >45 kg (>100 lbs). Equally surprising

North American Megafauna Extinction: Climate or Overhunting?, Table 1 Extinct genera and their common names, with radiocarbon dates (and calibrated ages in parentheses) which may mark the approximate time of their last appearances in North America

Family	Genus	Possible last appearance date in radiocarbon years BP (approx. midpoint of calibrated years BP)
Pampatheriidae	*Pampatherium* (southern pampathere)	Not available
	Holmesina (northern pampathere)	21,150 ± 400 (25,400)
Glyptodontidae	*Glyptotherium* (Simpson's glyptodont)	23,230 ± 490 (27,428)
Megalonychidae	*Megalonyx* (Jefferson's ground sloth)	11,485 ± 40 (13,336)
Megatheriidae	*Eremotherium* (Laurillard's/ Rusconi's ground sloth)	38,860 ± 1300 (42,861)
	Nothrotheriops (Shasta ground sloth)	11,020 ± 200 (12,910)
Mylodontidae	*Paramylodon* (Harlan's ground sloth)	12,333 ± 33 (14,285)
Mustelidae	#*Brachyprotoma* (short-faced skunk)	13,740 ± 145 (16,607)
Canidae	#*Cuon** (dhole)	Not available
Ursidae	*Tremarctos** (Florida cave bear)	23,230 ± 490 (27,428)
	Arctodus (Giant short-faced bear)	10,870 ± 75 (12,760)
Felidae	*Smilodon* (saber-toothed cat)	11,130 ± 275 (13.003)
	Homotherium (scimitar cat)	13,970 ± 310 (17,500)
	Miracinonyx (American cheetah)	14,935 ± 610 (18,100)
	*Panthera** (American lion)	11,355 ± 55 (13,150)
Castoridae	*Castoroides* (giant beaver)	10,850 ± 60 (12,750)
Hydrochoeridae	*Hydrochoerus** (Holmes' capybara)	12,000 ± 300 (13,850)
	Neochoerus (Pinckney's capybara)	Not available
Leporidae	#*Aztlanolagus* (Aztlan rabbit)	>31,150
Equidae	*Equus** (American horse)	10,870 ± 45 (12,750)
Tapiridae	*Tapirus** (tapir)	10,940 ± 100 (12,900)
Tayassuidae	*Mylohyus* (long-nosed peccary)	11,860 ± 40 (13,700)
	Platygonus (flat-headed peccary)	11,060 ± 60 (12,900)
Camelidae	*Camelops* (Yesterday's camel)	11,180 ± 45 (13,000)
	Hemiauchenia (large-headed llama)	12,210 ± 430 (14,400)
	Palaeolama (stout-legged llama)	10,890 ± 130 (12,800)
Cervidae	*Navahoceros* (mountain deer)	12,860 ± 400 (15,400)
	Cervalces (stag-moose)	10,800 ± 45 (12,700)
Antilocapridae	#*Capromeryx* (diminutive pronghorn)	12,200 ± 200 (14,300)
	Tetrameryx (Shuler's pronghorn)	23,230 ± 490 (27,400)
	Stockoceros (pronghorn)	12,520 ± 200 (14,650)
Bovidae	*Saiga** (saiga)	Not available
	Euceratherium (shrub-ox)	11,630 ± 150 (13,400)
	Bootherium (helmeted musk ox)	10,980 ± 80 (12,900)

(continued)

N

North American Megafauna Extinction: Climate or Overhunting?, Table 1 (continued)

Family	Genus	Possible last appearance date in radiocarbon years BP (approx. midpoint of calibrated years BP)
Gomphotheriidae	*Cuvieronius* (gomphothere)	11,550 ± 60 (13,400)
Mammutidae	*Mammut* (American mastodon)	10,630 ± 80 (12,600)
Elephantidae	*Mammuthus* (mammoth)	10,710 ± 130 on mainland (12,500)
		5600 ± 600 on St. Paul Island (6300)

Note that some of these dates are not universally accepted, because they were not made directly on bones or dung from the genera. References are in Barnosky et al. (2004), Faith and Surovell (2009), and Surovell et al. (2016: www.pnas.org/lookup/suppl/ https://doi.org/10.1073/pnas.1504020112/-/DCSupplemental). An *asterisk* in the table indicates a genus which survived outside North America. Four genera which are not megafauna are marked #. Date calibrations were performed online at http://intcal.qub.ac.uk/calib/

is that the extinctions affected taxa with very different diets – including herbivores which were grazers, browsers, and mixed feeders, as well as carnivores – living in a wide range of distinct ecozones. Not only were the extinctions unusual in being so biased toward animals of large body size and so unselective for feeding habits; they also seem abrupt. The last dated appearances of close to half the extinct genera fall between ~12,000 and 10,000 radiocarbon years before the present (~13,800–11,500 cal BP) in the lower 48 United States, in what has been termed as "synchronous" extinction event (Faith and Surovell 2009). Some extinct megafaunal genera might have disappeared earlier than that, but reliable dates on those fossil taxa are much too few to be sure. One species of the megafaunal genus *Mammuthus* (*M. primigenius* = woolly mammoth) actually died out much later than the other three species (*M. columbi* = Columbian mammoth, *M. jeffersonii* = Jeffersonian mammoth, *M. exilis* = pygmy mammoth), in the mid-Holocene, on a remote Bering Sea island (Graham et al. 2016).

These extinctions are even more extraordinary when compared to North America's earlier extinctions. They are not part of a "mass" extinction, as were the earlier ones, because of the clear size selectivity and the extremely wide variety of other animals that did not die out, particularly reptiles, medium-size and small mammals, and fish. Some bird genera disappeared around the same time, but many of them were scavengers which probably could not survive the loss of so much terrestrial carrion.

The Current Debate

Several possible explanations for the extinctions have been advanced, such as a disease capable of jumping species and spreading through the genera that became extinct, brought by dispersing humans or perhaps their dogs. Hyper-lethal disease organisms may or may not have been introduced by human dispersal into late Pleistocene North America, but clear evidence for pathogens in all the extinct genera and for an ability to jump to so many different species have not been identified. Another proposed explanation is that a meteoritic impact or huge airburst event from a meteor or comet(s) occurred over the eastern Canadian ice sheets about 12,900 calibrated years ago (Firestone et al. 2007), creating a powerful explosion and aftermath like nuclear winter, wiping out many species of large animals and severely challenging human survival; however, disagreements have been plentiful over whether true stratigraphic markers of such an explosive event have been correctly identified. Further weakening this hypothetical explanation is the fact that some megafauna which were present at the time in North America such as brown and black bear (*Ursus* spp.), whitetail and mule deer (*Odocoileus* spp.), and moose (*Alces alces*) did not become extinct.

A much more popular explanation for the dieouts is the cycle of major climate changes occurring before the megafauna disappeared. Global ice sheets had grown to maximum sizes between 33,000 and 26,500 calibrated years ago, holding steady until they began melting after 19,000 years ago. Climatic oscillations over the next nine

North American Megafauna Extinction: Climate or Overhunting?, Table 2 Major climatic intervals in the northern hemisphere during the last part of the Pleistocene, cited in radiocarbon years and also "ka," indicating thousands of calendar years before year 2000

Climatic interval	Approx. radiocarbon age (approx. age in calendar years)	General characteristics
Last Glacial Maximum	23,000–18,000 (26.5–19 ka)	Cold, dry
End of Last Glacial Maximum	16,000 (19 ka)	Warming
Bølling	12,500 (15 ka)	Relatively warm, moister
Older dryas	12,000 (13.8 ka)	Cool
Allerød	11,500 (13.3 ka)	Warmer, moister
Younger dryas begins abruptly	11,000 (12.9 ka)	Cold

millennia (Table 2) would have periodically stressed megafaunal populations in the northern hemisphere, by reducing optimal food resources and removing the connectivity between patches of different resources. This might seem to be the most obvious solution to the extinction mystery, but the storyline has been challenged by scientists who emphasize two important facts: (1) Similar cycles of climatic changes had already occurred several times over the past two million years, yet they had not led to such extinctions; and (2) a completely new factor had appeared just before the time of the extinctions: the earliest humans had dispersed into North America from Asia, according to the most credible archeological and genetic evidence.

The two leading hypotheses for explaining the extinctions – climate change and human effects – need to be sized up against each other.

One Hypothesis: Climate Change Caused the Extinctions

Climate change is almost a default explanation for the cluster of selective extinctions, especially among scientists who do not think mobile human foragers armed only with stone-tipped spears and at low population densities could have eradicated megafaunal populations in an entire continent.

The sizes of megafaunal populations after the Last Glacial Maximum are unknown, although geographical distributions seem to be broad (FAUNMAP Working Group 1994). During the last millennia of the Pleistocene, climates shifted dramatically (Table 2), and these shifts must have greatly affected megafaunal ranges when preferred forage plants were locally extirpated or redistributed in the continent. Different subpopulations of animals may have been depleted to relatively low numbers due to the disruption and the displacement of vegetational communities in response to the climatic oscillations. Yet even relatively widespread genera abruptly died out; the extinctions did not preferentially affect only the genera whose geographic ranges had been seriously reduced.

Several researchers have suggested possible ecological processes through which megafaunal taxa were driven to extinction during this difficult interval of ever-shifting climatic conditions. For example, Guthrie (1984) proposed that the trend toward zonal vegetation replacing highly diverse mosaic plant communities at the end of the Pleistocene reduced nutrient balance and plant diversity, forcing megafauna to feed more heavily on limited types of plants whose antiherbivory chemical compounds were harmful in higher doses, eventually leading to population crashes and extinctions of large-bodied animals with specialized diets.

This proposal is reasonable to explain extinctions in some parts of the continent, but not all. The main problem with attributing the extinctions only to climate change is that no unidirectional set of paleoenvironmental changes affected all of North America at the end of the Pleistocene. In some parts of the continent, open habitats expanded at the expense of woody habitats, while in other parts, woodlands and forests began replacing the more open environments of

the Pleistocene. Thus, diverse megafaunal foraging opportunities did not vanish from the entire continent, although the megafauna did vanish everywhere. Isotope studies show there was geographic variability in megafaunal diets, implying that at least some genera were capable of switching diets to take advantage of local vegetational communities. The complete disappearance of so many grazers, browsers, and mixed feeders during a period of variably responding plant resources is not easily explained.

New analytical methods have been applied to pinpoint a cause in nature, but these tend to contribute even more uncertainty. For example, ancient DNA (aDNA) recovered from bones of extinct megafauna of known ages have been analyzed to identify the times when genetic diversity had dramatically dropped; the implication is that when climate-caused fragmentation of animal populations led to lowered genetic diversity such as by the disappearance of haplotypes from the genome, the proportions of deleterious traits would have increased in subpopulations, fecundity would have dropped, and rates of developmental problems would have risen. These genetic problems are assumed to be harbingers of extinction drawing near. But interestingly, some taxa which survived the extinctions such as *Ursus* (bear) and *Canis lupus* (wolf) are today genetically less diverse than some genera which did go extinct. Thus, while a loss of genetic diversity implies that the continental populations of some genera had been fragmented, by itself it does not mean those genera were inevitably doomed to extinction.

Furthermore, aDNA studies of several extinct northern North American genera (*Panthera* [lion], *Mammuthus*, *Ursus*, *Equus* [horse]) (Ersmark et al. 2015 and references therein) show that while genetic diversity had indeed dropped in those genera before the Last Glacial Maximum, their genetic diversity later began recovering in the time interval just before the first appearance of humans. Perhaps just as importantly, not every extinct genus had suffered reduced genetic diversity just before extinction, such as the flat-headed peccary *Platygonus compressus* (Perry et al. 2017), making it unlikely that this genus was in decline or had been fragmented for long into isolated subpopulations. This genus vanished without showing the signs of climate-induced genetic problems.

Another argument is sometimes advanced to support the serious effects late Pleistocene climate changes had on megafauna: The body sizes of some genera were larger before the extinctions, implying that environmental stresses such as declines in optimal forage were forcing major evolutionary changes which some genera perhaps could not attain quickly enough. For example, the body size of one extinct genus in Alaska, *Equus*, rapidly declined in the late Pleistocene before becoming extinct, construed as indirect evidence of climate-caused ecological stress in response to depressed forage productivity (Guthrie 2003). However, shrinking body size, like reduced genetic diversity, was survived by other large mammals which faced the changing conditions of the late Pleistocene. Modern elk (*Cervus elaphus*) and bighorn sheep (*Ovis canadensis*) in the Northwestern USA and *Bison* in the mid-continent had larger body sizes in the Pleistocene than in the Holocene, but they are still with us. Shrinking body size due to climate change indicates that genera were capable of re-adapting to changing vegetational communities.

A Competing Hypothesis: Humans Caused the Extinctions

Climate change to account for extinctions has not been proven completely wrong, but it does not seem possible to prove it completely right, either. Ever since the nineteenth century, a competing hypothesis has been gaining support – the view that hunting by humans was the decisive factor that led to the extinctions (a concept termed "overkill"). The first hints that humans were contemporaneous with the extinct animals were discovered in the early and mid-1800s, and scientists began debating whether Stone Age humans could have destroyed so much animal life. The overkill hypothesis has had varying degrees of acceptance within the scientific community, but its appeal expanded in the 1960s and afterward when

paleoecologist Paul Martin (e.g., 1984) presented a vigorous series of arguments pointing out that so many megafaunal genera had survived multiple episodes of severe climate changes for more than a million years. What the large animals could not survive, according to Martin and adherents, was the appearance of modern *Homo sapiens* in their ranges. The worldwide dispersal of modern *Homo sapiens* had begun ~60,000 years ago, and it is in this period of global colonization that most extinctions occurred in each continent and island, one after another. The extinctions correlate well with the earliest human presence in most landmasses, but they do not correlate well with climate changes on those landmasses.

Human influence on the extinctions may have been on multiple levels. Habitat alterations such as deliberate burning by dispersing human foragers would have had adverse impacts on megafaunal species. Killing by humans also would have been a significantly destructive factor. Partial support for the overkill hypothesis can be found in the fossil record; for example, the geographical distribution of North American *Mammuthus* was actually more extensive in the climatically ameliorating interval of the Late Glacial (15,000–10,000 radiocarbon years BP) than during the earlier severe conditions of the Last Glacial Maximum (Agenbroad 2005), suggesting population recovery for this genus just before its extinction, around the time of the most widespread appearance of early human cultures.

In Paul Martin's favored variant of the overkill hypothesis, known as "blitzkrieg" or explosive overkill, the rapidly dispersing population of new human arrivals in the New World encountered large mammals that were naively ineffective at escaping from such an unfamiliar new predator, and human hunting as it spread over the continent steadily decimated the animal populations in a short time. Martin's critics pressed him to explain the almost absolute lack of kill sites of most of the extinct megafaunal genera in North America, but Martin had reasoned that kills made so quickly would not be expectably preserved in open-air sites, other than from animals with bones as massive as those of mammoths and mastodons, except in unusual circumstances. This is not an empirically testable hypothesis, but it is in agreement with observations from long-term neotaphonomic fieldwork that has documented the rarity of animal skeletons in unsettled parts of the world as bones are consumed by scavengers, scattered to become undiscoverable over time, or weather away (e.g., Haynes 1980).

It is true that direct evidence is scarce for human killing of most of the extinct megafaunal taxa (Table 3), but the numbers of kill sites are still impressive when their dating is considered; a geologist might see most of them as near-coincidental. More than a dozen sites in North America are generally accepted as human-made kills of mammoths, mastodons, and gomphotheres, and many more have been claimed as kills but are not universally accepted. The total number of all megafauna – proboscidean and non-proboscidean – in these possible kill sites is 112, of which 84 are the elephant-like animals (*Mammuthus*, *Mammut*, and *Cuvieronius*). The number of sites claimed to be proboscidean kills in Table 3 is nearly one-fifth of the total number of all reported proboscidean bone sites dating to the Late Glacial interval, according to the online Faunmap database (http://www.ucmp.berkeley.edu/faunmap/), implying human predation was a major cause of deaths in this time.

In a few cases, mammoth sites with associated stone tools might have been scavenged by humans after the animals were found dead, but the discovery of killing implements (stone spear points) in sites along with cutmarks on meat-bearing bones from sites such as Blackwater Draw, Dent, and Duewall-Newberry (Krasinski 2010) indicate many if not all of the animals were actively killed by humans. Saunders (1980) proposed that some multi-mammoth sites were the remains of family groups killed together by human hunters, but analyses of isotopes in mammoth teeth from several of these sites (Hoppe 2004; Fisher and Fox 2007) have revealed the accumulations are probably the remains of individual animals from different family groups which had been killed in separate events. Although the physical efforts needed to pursue, kill, and process prey animals as huge as mammoths may have been high, the archeological record shows that humans did preferentially select the largest megafaunal taxa, deliberately choosing

North American Megafauna Extinction: Climate or Overhunting?, Table 3 North American extinct megafaunal sites claimed to be kills made by humans; some have been doubted

Site	Prey genus and species	Cultural association and radiocarbon date(s) (BP)
Ayer Pond, WA	*Bison antiquus*, MNI = 1	No lithics, possibly human-broken bones; 11,990–11,700
Blackwater Draw, NM	*Mammuthus columbi*, MNI = 6; *Bison antiquus*, MNI = 1	Clovis lithics, butcher-marked bones; 11,040–11,630
Burning Tree, OH	*Mammut americanum*, MNI = 1	No lithics; possibly butcher-marked bones; 11,660 and 11,450 on possible gut contents, 10,860 on mammoth bone
Coats-Hines, TN	*Mammut americanum*, MNI = 1	Untyped lithics (flakes, scrapers, biface, gravers); disturbed sediments, wide date range (27,050–6,530)
Colby, WY	*Mammuthus columbi*, MNI = 7; *Camelops hesternus*, MNI = 1; *Equus* sp., MNI = 1	Clovis lithics; 11,220; 10,864
Dent, CO	*Mammuthus columbi*, MNI = 15	Clovis lithics, butcher-marked bones; 11,200; 10,980–10,670
Domebo, OK	*Mammuthus columbi*, MNI = 1	Clovis lithics; ~11,000
Duewall-Newberry, TX	*Mammuthus columbi*, MNI = 1	No typed lithics, possibly butcher-broken and marked bones; estimated 12,000–10,000
Dutton, CO	*Mammuthus columbi*, MNI = 1; *Equus* sp., MNI = 1	Clovis lithics; <11,710
Escapule, AZ	*Mammuthus columbi*, MNI = 1	Clovis lithics; no direct date
El Fin del Mundo, Mexico	*Cuvieronius* sp., MNI = 2	Clovis lithics; 11,550
Hebior, WI	*Mammuthus primigenius*, MNI = 1	Untyped lithics; possibly butcher-marked bones; 12,480–12,590
Heisler, MI	*Mammut americanum*, MNI = 1	No lithics, possibly butcher-marked bones; 11,770
Hiscock, NY	*Mammut americanum*, MNI = 6	Clovis points; 9,150–11,390
Huntington Canyon, UT	*Mammuthus columbi*, MNI = 1; *Arctodus simus*, MNI = 1	Non-Clovis projectile point possibly from same stratum as mammoth; 11,220
Kimmswick, MO	*Mammut americanum*, MNI = 2	Clovis lithics; no direct date
Lange-Ferguson, ND	*Mammuthus columbi*, MNI = 2	Clovis lithics, possibly human-broken bones; no direct date
La Prele, WY	*Mammuthus columbi*, MNI=1	Untyped flake tools, bone needles, bone bead, lithic chopper with proboscidean residue, red ocher pieces; multiple Clovis-age dates
Lehner, AZ	*Mammuthus columbi*, MNI = 13	Clovis lithics; 10,900
Leikum, AZ	*Mammuthus columbi*, MNI = 2	Clovis lithics; no direct date
Lindsay, MT	*Mammuthus columbi*, MNI = 1	No lithics, possibly cutmarked bones; 12,330 – 12,105
Lubbock Lake, TX	*Mammuthus columbi*, MNI = 2(?)	Clovis lithics; 11,100
Manis, WA	*Mammut americanum*, MNI=1	Possible bone projectile point embedded in a rib; 11,800
Miami, TX	*Mammuthus columbi*, MNI = 5	Clovis lithics; between 11,400 and 10,500
McLean, TX	*Mammuthus columbi*, MNI = 1	Questionably associated Clovis point; no date
Murray Springs, AZ	*Mammuthus columbi*, MNI = 2; *Bison antiquus*, MNI = 13	Clovis lithics; 10,900
Naco, AZ	*Mammuthus columbi*, MNI = 1	Clovis lithics; no direct date
Navarette, AZ	*Mammuthus columbi*, MNI = 1	Two Clovis points; no direct date

(continued)

North American Megafauna Extinction: Climate or Overhunting?, Table 3 (continued)

Site	Prey genus and species	Cultural association and radiocarbon date(s) (BP)
Norwich Township, OH ("Firelands Ground Sloth")	*Megalonyx jeffersonii*, MNI = 1	No lithics, possible toolmarks from meat-stripping; 11,740 ± 35
Page-Ladson, FL	*Mammut americanum*, MNI = 1	Non-Clovis lithics, possibly cut tusk; 12,450 (average of 6 dates)
Pleasant Lake, MI	*Mammut americanum*, MNI = 1	No lithics, possibly butcher-marked bones; >10,395
Rawlins, WY ("U.P. Mammoth")	*Mammuthus columbi*, MNI = 1	Untyped lithics; 11,280
Santa Isabel Ixtapan, Mexico	*Mammuthus columbi*, MNI = 1	Lithics, possibly associated non-Clovis projectile point; no direct date
Schaefer, WI	*Mammuthus primigenius*, MNI-1	Untyped lithics, possibly butcher-marked bones; 12,390–12,310
Sloth Hole, Aucilla River, FL	*Mammut americanum*, MNI = 1+	Fluted point variants, lithics, bone tools, 33 ivory points; no direct date
Wally's Beach, Alberta	*Camelops hesternus*, MNI = 1; *Equus* sp., MNI = 7	Possibly butcher-marked bones, untyped lithics; possible blood residue on lithics; 11,070

For more information and references, see Haynes (2002, 2015) and Surovell and Waguespack (2009). "Clovis" lithics refers to typologically distinct stone artifacts of the Clovis era; the sites of this era have been dated 11,550–10,800 radiocarbon years BP (roughly 13,400–12,700 calibrated years ago) (Waters and Stafford 2007). Other sites may belong on this list. "MNI" in the table refers to minimum number of individuals

to bypass the more abundant and easier-to-kill smaller species at certain times and places (Surovell and Waguespack 2009). Human foragers possibly sought not only food from the largest animals but also the added prestige associated with the ability to kill such imposing creatures.

Future Directions in the Search for a Cause

It is anything but clear what ultimately caused the extinctions. Lately the trend in interpretations has been toward a dual causality model for extinctions on several continents and landmasses, in which range restrictions and limited genetic connectivity among metapopulations – the results of oscillations in climate and vegetation – were made much deadlier by the addition of modern *Homo sapiens*, and the two factors together led to the disappearance of the large mammals. This dual causality concept has gained traction among scientists who realize that theories of single causes, such as climate change or hunting by humans, are by themselves imperfect. The synergistic interplay of climate stresses and human impacts will have to be painstakingly worked out separately for each extinct taxon (Barnosky et al. 2004), but it does appear that the extinctions' tipping point in North America was the entry and spread of *Homo sapiens*.
